Dr. Sydney R. Miller proceeded with his report "The Committee on Credentials has reviewed 4 applications for reinstatement, and, after due consideration, moves the adoption of the following resolution

"*Resolved*, that in accordance with the rules and regulations governing reinstatement, the following be and herewith are reinstated as Fellows of the American College of Physicians—Dr. Clarence Henry Beecher, Burlington, Vt., Dr. Gilbert E. Brereton, Dallas, Tex., Dr. William H. Stewart, New York, N. Y., and Dr. Julius Ullman, Buffalo, N. Y.

"The motion was seconded by Dr. Charles H. Cocke, and unanimously carried."

Dr. George Morris Piersol, Chairman of the Committee on Advertisements and Commercial Exhibits, reported as follows "This Committee, after due consideration, has drawn up certain fundamental principles that they recommend for adoption to govern the College in the matter of exhibitors at the Annual Convention, namely

"(1) Exhibitors shall be admitted on invitation only,

"(2) The initial approved 'Invitation List' shall be made up by the Committee and the Executive Secretary. Both the firm and the product must be approved

Preference shall be given to exhibits of a scientific nature, such as pharmaceuticals, equipment and medical books,

"(3) Additions to the initial approved 'Invitation List' may be made by the Committee after application by firms, with the requirement that they submit complete literature concerning their products and their organization

"(4) The 'Invitation List' may be revised annually on the recommendation of the Committee"

Dr Piersol said that if such rules are adopted, it will give the Executive Secretary ample latitude in the regulation of exhibitors and in the exclusion of exhibits irrelevant to the practice of Internal Medicine or one of its allied specialties

On motion by Dr James E Paullin, seconded by Dr Roger I Lee, and unanimously carried, it was

Resolved, that the recommendations of the Committee on Advertisements and Commercial Exhibits be approved

Dr Maurice C Pincoffs, Chairman of the Committee on Revolving Loan Fund, reported as follows "The Committee on Revolving Loan Fund, at a special meeting, has discussed in detail a project which we would like to submit at this time not for adoption, but for approval in principle, feeling that if it is thus approved, it will merit going into the laborious task of reducing it to a form where it could be considered and adopted at a later meeting The Committee feels that the principle of establishing a Revolving Loan Fund is justified, because the College has added to the difficulties of young men preparing themselves for Internal Medicine, and there is danger that those difficulties may keep from Internal Medicine valuable men, both in character and ability It is especially fitting, therefore, that the College should, within its means, attempt to aid that group of unknown size who may otherwise be deterred from going into Internal Medicine We feel that we should attempt to aid them only insofar as we have or shall have added to their obstacles In other words, if we consider, in a rough way, that we have added about two years to the average term of preparation, we should not attempt to carry a man through the whole period of training of five years, but only through the two additional years for which we have been responsible It is also advisable because any longer period complicates the economics of the plan, and will be an undue burden of debt upon any young man who would wish to take advantage of it The mechanism for putting the Loan Fund into effect is that this Board, or the President, as may be deemed advisable appoint in each Class A medical school a representative from among those Fellows or Officers of the College that are attached to that school who will assume the burden of forming his local committee to receive applications for aid from young men, either during their graduate work in that school or in that territory in other institutions The filling out of blanks carefully, looking into the character and ability of the applicant and into his needs would fall upon each local committee The application then should come to the standing committee, analogous somewhat to the Committee on Credentials A standing committee of that type should meet semi-annually to consider applications coming from the different sections of the country, and pass upon them both in relation to their merit and to the funds available

"Some preliminary study has been made of the question of funds and the manner in which a Revolving Loan Fund works (Dr Pincoffs thereafter passed around a chart) To make it specific, a project has been worked out for four men, two for two years at \$1,000 00 a year each, and two for two years at \$500 00 a year each This would entail an expenditure over a period of eleven years before the Fund would first become self-supporting of somewhere around \$3,500 00 a year average After eleven years it would become somewhat better than self-supporting, and if at any time it should stop, the payments going on would pay back to the College in the course of another eleven years what had been put into it

"It would be possible, with a sum approximating \$8,000 00 a year, to run units of a minimum of sixteen men. I say 'a minimum' because that figure of sixteen is based on our giving the maximum aid to each man, whereas it would be our endeavor to give such aid as should be urgently needed. ~~probably the number aided would be far in excess of sixteen. I may say that this is felt to be in the nature of an experiment.~~ I have consulted the Harmon Foundation, which has had a rather extensive experience in student loan work. As far as it is aware, there has been no loan fund of exactly this kind for graduate medical men, although some graduate medical men have received loans from funds devised for general aid for students. Our suggestion is in the nature of an experiment, which the College can cut short within a year, because the loans only extend over two years and the maximum amount is never such as would be crippling, and the yearly outlay, we feel, whether we start with \$4,000 00 or \$8,000 00, is something that our recent surplus could afford. The Committee feels that a more detailed plan in writing should be submitted to the Regents. The Committee, however, presents this interim report and hopes that the suggestion may be approved, if it seems feasible, or the plan discarded before any further work is put on it.

The College has been instrumental in adding to the requirements for entering Internal Medicine by raising its standards of admission to Fellowship and by initiating the American Board of Internal Medicine. It is felt that men will often require aid in their last two years before coming up for certification. The plan is based on allowing two years after certification before any beginning of repayment is made. The sum arbitrarily set for them to pay is at the rate of \$20 00 a month, or \$240 00 a year, which in the smaller loans enables them to make full repayment in a little over five years, and in the maximum loan, enables them to make repayment in ten years. It would never exceed ten years, and the Committee feels that it would often be under five."

There was general discussion of the report, with some consideration of the possibility of losses. From the experience of other loan funds, losses have been negligible, arising mainly due to death.

On motion by Dr. James Alex. Miller, seconded by Dr. James B. Herrick, and unanimously carried, it was

Resolved, that it be the sense of the meeting of the Board of Regents at the present time that the plan offers very interesting possibilities, and that the Committee be instructed to go ahead with the further details for the development of a completed plan.

Dr. David P. Barr, Chairman of the Committee on Fellowships and Awards, reported that the Committee had duly considered a number of names submitted as candidates for the John Phillips Medal. He read a list of the names of the men who had been considered, and discussed in particular the names of those who had been most seriously considered.

On motion by Dr. Barr, seconded by Dr. James E. Paullin, and unanimously carried, it was

Resolved, that the 1938 award of the John Phillips Memorial Medal be made to Dr. Harry Goldblatt, of Cleveland, Ohio, in recognition of his having devised an important method for the production and study of experimental hypertension in animals, for his having demonstrated the significance of renal ischemia in the causation of high blood pressure, and for his having contributed significantly to the understanding of essential hypertension, one of the most common and disabling conditions encountered in medical practice.

Dr. Barr proceeded with the second part of his Committee's report, in regard to a number of candidates considered by the Committee this year for the American College of Physicians' Research Fellowship. Only eight applications had been con-

sidered, and it was decided that the Committee would recommend only one Research Fellowship, this to be awarded to John Russell Smith, who, since his graduation, has served as Intern and Assistant Resident at the Barnes Hospital, St. Louis, and who has been engaged in research, most of the time, with Dr. W. B. Kuntz, in problems of circulation and respiration. His most recent work has been with Dr. Kuntz, conducting observations on peripheral vascular diseases. Dr. Smith desires to go to Professor Anrep in Egypt to pursue his studies, particularly of circulation and respiration.

On motion by Dr. Barr, seconded by Dr. W. D. Stroud, and unanimously carried, it was

Resolved, that a Research Fellowship in the amount of \$1,800.00 for 1938-39, beginning July, 1938, be awarded to Dr. John Russell Smith.

Dr. Barr reported that it was the hope of the Committee that in not presenting a candidate for the second Research Fellowship for 1938-39 that the fund may be so earmarked that the following year, given suitable candidates, the Committee might recommend three men instead of two.

Dr. O. H. Perry Pepper made the suggestion that the Committee consider doing something to find positions for the recipients of fellowships after the period of fellowship has expired. Dr. Barr was in agreement with this suggestion.

On motion by Dr. Barr, seconded by Dr. Jonathan C. Meakins, and unanimously carried, it was

Resolved, that the fund of \$1,800.00 not expended for 1938-39 for a second Research Fellowship be, nevertheless, appropriated for use for a third Fellowship during 1939-40, if desirable.

On motion by Dr. Barr, seconded by Dr. James E. Paullin, and unanimously carried it was

Resolved, that the College shall place at the disposal of each recipient of a Research Fellowship any part of the fund which the recipient may need at the beginning of his fellowship, so that it may be used for necessary expenditures in transportation, etc., subject to the recommendation of the Committee.

Dr. James Alex. Miller, Chairman, reported for the Committee on Future Policy for the Development of Internal Medicine.

"(1) The Committee recommends that the Regents request the Executive Secretary to look into the matter of liability insurance for members of the College from various angles and report to the Committee."

On motion by Dr. Miller, seconded by Dr. O. H. Perry Pepper, and unanimously carried, it was

Resolved, that the above recommendation be carried out.

"(2) The Committee recommends that the Board of Regents appoint a special committee to study the matter of graduate education in cooperation with the American College of Surgeons. Also, that the Regents consider the possibility of creating a standing committee on graduate education."

There was some discussion of this subject, Dr. Pincoffs spoke in favor of the idea of having a standing committee created, not necessarily of the Regents alone, but one including any member of the College particularly valuable for such work. Dr. James D. Bruce said that he would very strongly recommend that a committee of "this body be named, which can and may collaborate with the various national committees when and if their advice and assistance may be called for."

On motion by Dr. James Alex. Miller, seconded by Dr. Walter L. Bierring, and unanimously carried, it was

Resolved, that the Board of Regents authorize the appointment of a committee by the President of a size which he may select, not necessarily confined to members

"Vigorously scientific . . .

entirely adequate in its scope and detail" . . .

MILITARY SURGEON

TWENTY years of experiences in the **THYROID CLINIC** of Massachusetts General Hospital, by the author and collaborators, make this work practical, scientific and authoritative

This book is concerned primarily with the medical and pathologic aspects of the subject. Interesting throughout, the author discusses the gland, the hormone, the relation of the thyroid to its endocrine partners and the pathology and symptomatology of the thyroid. Methods of examination are given, classification, simple goiters, myxedema and cretinism. Toxic goiters are considered (including iodine response and surgery), nodular, malignant and inflammatory goiters. Anomalies of the Thyroid are discussed (including Intrathoracic Goiters and the various Ectopic or Aberrant Thyroids), Thyroid Administration and total thyroidectomy in diseases of other than thyroid origin. 602 pages 73 charts and illustrations \$6 00. Priced slightly higher in Canada.

Chief of Medical Services, Massachusetts General Hospital.*

**NEW
BOOK**

**INVALUABLE, and the
only book of its kind . . .**

DR McBRIDE'S **DISABILITY EVALUATION** is a *guide* to the accurate evaluation of disability—so that great discrepancies may be avoided in the testimony of expert witnesses. Workmen's Compensation Laws for every state are abstracted. Dr McBride discusses those injuries most often encountered, and by *analysis of function*, gives a guide to the measurement of disability following single or multiple injuries. Much attention is given to examinations, signs and symptoms, as well as to the disabilities of the member. Nerve, Head, Eye and Ear injuries are covered, as well as Amputation, Burns and Hernia, with the evaluation of the disability in each case. New Second Edition 640 pages 374 illus \$8 00

*Editorial Advisor***Jones****DIGESTIVE TRACT PAIN****Diagnosis and Treatment****Just
Published****\$2 50**

It is the purpose of this book to present a study of pain and other similar sensations caused by disturbances of the digestive tract. The accurate diagnosis and treatment of gastro-intestinal disorders depend in large part upon a proper evaluation of the symptoms which the patient presents. Of these, pain is the outstanding one. In addition to this study, the author has added a group of clinical observations having a direct bearing upon the production and diagnosis of alimentary tract pain.

Forkner**LEUKEMIA AND ALLIED DISORDERS**

This volume fills a long felt need for a comprehensive monograph on leukemia. The disease is poorly understood and there has been much confusion regarding terminology, classification, etiology, natural history of the disease and its pathologic physiology. In this book the fundamental aspects of the problem are discussed with special reference to the pathologic physiology of the blood and the blood-forming organs and its bearing on the structure and function of the organism as a whole.

BUFFERED ALKALINIZATION

by the safe, physiological process

WHERE buffered alkalinization is desirable—as during sulfanilamide administration, in the treatment of colds, influenza and other seasonal respiratory affections—Kalak offers these clinical advantages

(1) It presents a balanced combination of bicarbonates in solution (2) It contains the mineral substances normal to the blood (and no other)

Kalak's high buffering value helps to maintain the urinary pH of 7.4 which has been found so desirable in sulfanilamide therapy

KALAK is synthetically prepared—is hypertonie, uniform in composition, definite in alkali potency

KALAK WATER COMPANY OF NEW YORK, INC., 6 CHURCH STREET NEW YORK CITY

The new "All-Electric" models are made in stationary, mobile and portable types for hospitals, clinics and private offices

You get what you pay for

IN the Electrocardiograph—as in everything else—we *get what we pay for*. Some manufacturers put quality first—others price. The latter may speak of their products as "good enough" what they mean is "good enough for the price."

The Medical Profession recognizes nothing as merely "good enough." It is constantly striving to improve skill in diagnosis and treatment. Diagnosis in cardiac cases must be accurate. To that end Cambridge recognizes nothing as just "good enough" in the construction of the *Hindle*. All parts are designed, manufactured and assembled with the utmost care for quality of materials and workmanship.

This results in an Electrocardiograph possessing accuracy, dependability and long life—an instrument far better than just "good enough!" Send for Literature

SOME IMPORTANT OXFORD MEDICAL BOOKS

PSYCHIATRY FOR PRACTITIONERS

By Various Authors Edited by Henry A. Christian, A.M., M.D., LL.D., Sc.D. (Hon.)
652 Pages Cloth \$6.50

Believing that there is a definite, very considerable need by *practitioners of medicine* for a better knowledge of psychiatry, this volume has been prepared for that end.

DISEASES OF THE NEWBORN

By Abraham Tow, M.D.
477 Pages 53 Illustrations Cloth \$6.50

There is a real need among those who treat the newborn for an authoritative work dealing with the many phases of the problem—a work suitable for the obstetrician, the pediatrician and particularly for the general practitioner who finds it necessary to combine the duties of both.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE PERIPHERAL ARTERIES

By Saul S. Samuels, A.M., M.D.
275 Pages 51 Illustrations Cloth \$3.50

This book comprises an entirely new approach to a branch of medicine and surgery that has never before been adequately covered in any one volume. It deals with the important subjects of diabetic gangrene, intermittent claudication and thrombo-angitis obliterans and gives detailed descriptions of methods of diagnosis and treatment based on the author's large experience.

THE PHYSIOLOGY OF THE KIDNEY

By Homer W. Smith, A.B., Ph.D., M.S. (Hon.)
320 Pages 33 Illustrations Cloth \$4.50

The author's experience in the study of the comparative physiology of the kidney, combined with the numerous investigations which have been carried out in his laboratory on the renal function in man, enables him to present a broad and well integrated resume of this field. This volume makes its appeal to the student, the investigator, and the clinician.

APPLIED PHYSIOLOGY

By Samson Wright, M.D., F.R.C.P.
718 Pages 282 Illustrations and 2 Colour Plates Cloth \$6.00

This is the SIXTH edition of a physiological monograph that has received the approbation of the medical profession at large since its first publication in 1926.

THE MANAGEMENT OF THE PNEUMONIAS

By J. G. M. Bullock, B.Sc., M.D.
528 Pages 142 Illustrations Cloth \$8.50

Represents actual experience in the treatment of almost 8000 patients. It embodies a thorough study of etiology, diagnosis, prognosis, serotherapy, oxygentherapy, use of sulfanilamide, complications, and pneumonia in children. Profusely illustrated.

PATHOLOGICAL PHYSIOLOGY AND CLINICAL DESCRIPTION OF THE ANEMIAS

By William B. Castle, M.D., S.M. (Hon.), and George R. Minot, M.D., S.D. (Hon.), F.R.C.P., Edin. (Hon.)
214 Pages Cloth \$3.00

"I warmly commend it to practitioners of medicine"—Henry A. Christian, A.M., M.D., LL.D., Sc.D. (Hon.), Editor.

DISEASE AND THE MAN

By Roger F. Lapham, A.B., M.D.
142 Pages Cloth \$2.00

A book which meets the problem of that vitally important but very much neglected subject, the interrelation between treatment of the patient and treatment of his disease.

RADIATION THERAPY

By I. I. Kaplan, B.Sc., M.D.
586 Pages 198 Illustrations Cloth \$10.00

From an authoritative source comes an exhaustive analysis of the uses of X-ray and radium in the treatment of benign and malignant conditions. The book, because of its all embracing scope, makes the modalities valuable to student, practitioner, surgeon, and therapist. Profusely illustrated.

These and other monographs, including OXFORD LOOSE-LEAF MEDICINE, will be on display in our booth, 8, at the American College of Physicians meeting in New York.

DIAGNOSTIC ROENTGENOLOGY

Edited by **ROSS GOLDEN, M.D.**

Professor of Radiology, Columbia University, Director of Radiology, Presbyterian Hospital, New York

14 Eminent Contributors

The most comprehensive and complete volume ever published on the subject

Contents Skull and Intracranial Contents, Sinuses and the Mastoids, Radiology of the Chest, Cardiovascular System, Digestive Tract, Diseases of Bones, Spinal Cord Tumors, Urinary Tract, Obstetrics, Radiology of Fractures Gynecology

"It offers the most complete and comprehensive presentation of the subject of roentgen diagnosis available in English" *S G & O*, August 1936

Nelson Loose-Leaf Medicine

Published in nine volumes including Index Volume
Research Service and Consulting Bureau for Information

Editor-in-Chief **WILLIAM W. HERRICK, M.D., F.A.C.P.**
Professor of Clinical Medicine, College of Physicians and Surgeons, Columbia University, New York

Always Up-to-Date

The Nelson Practice of Medicine is arranged in loose-leaf form so that obsolete chapters may be removed and revised chapters inserted, that every new description may be incorporated in the volumes and every article be kept thoroughly up-to-date. Each subscriber receives five hundred or more new pages annually. The Nelson system is a living growing medical library—a mirror to present-day medicine.

Kept up to date every six months with 500 or more new or revised pages annually, practically a new volume each year. The volumes avoid duplication and overlapping of subjects, only accepted and approved medicine is published. Follow-up results are stressed, obsolete methods are eliminated from the discussion. Tested new procedures are advised. References to comprehensive bibliographies are given.

"It is an extraordinary achievement on the part of the editors of this loose-leaf surgery to have been able to maintain the production of renewal pages at such a high level for so many years. Assurance of the reliability of this service is the most eloquent of all recommendations of this work to the coming generation of surgeons."—*The Lancet*, March, 1935

"Early" is the watchword in

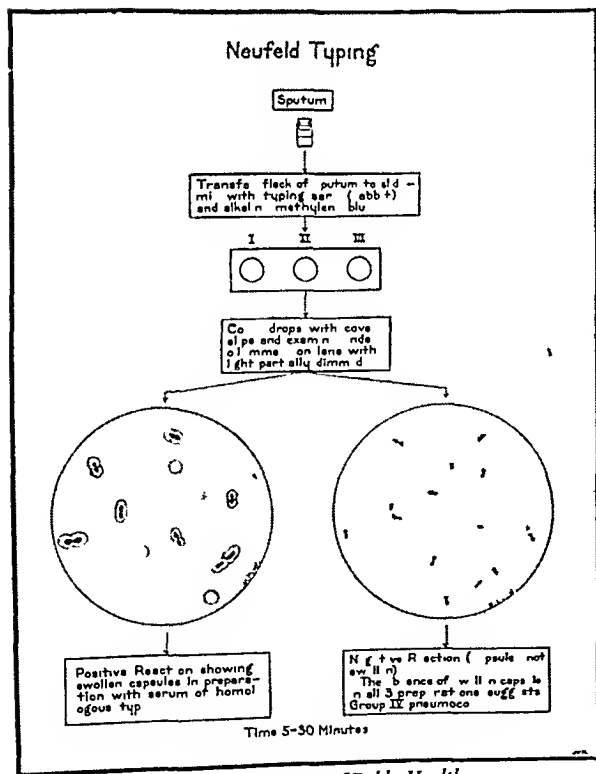

PNEUMONIA CONTROL

IN A RECENT ISSUE OF THE HEALTH OFFICER, the following watchwords were promulgated for the control of pneumonia

"Early diagnosis, early typing and early serum treatment mean early recovery"

The importance of *early typing* cannot be over-emphasized, for it not only serves to identify the specific etiologic agent of the pneumonia, but frequently, and especially in atypical pneumonias, it also aids in fixing the diagnosis and makes possible the early administration of specific serum

The Neufeld Rapid Typing reaction should be applied to the patient's sputum immediately upon suspicion of lobar or bronchial pneumonia

Courtesy Mass. Dept. of Public Health

"Pneumococcus Typing Serum Lederle" Types 1 to 32 for the Neufeld Reaction, ready for immediate use, are available in 10 cc vials and in packages of 5 capillary tubes for individual tests

An editorial in the December 4, 1937 issue of the Journal of the American Medical Association states

"In view of the distribution of pneumonia and the known effectiveness of serum when given early in the most fatal types, the facilities for typing are of the utmost importance"

A printed list of 2000 laboratories in the United States and Canada to which sputum may be referred by practitioners for typing has been published in directory form by Lederle and may be obtained free on request to

*Pneumonia control will be one of the subjects illustrated at the Lederle booth—
Convention of the American College of Physicians, April 4 to 8*

Announcing . . . for the higher pneumococcus types

ANTIPNEUMOCOCCIC RABBIT SERA

(Including Type 3)

THE DEVELOPMENT OF THERAPEUTIC RABBIT SERA for the higher type pneumococcus pneumonias is important news. Now physicians are afforded a specific measure for the treatment of pneumonia types some of which (notably Type 3) frequently terminate fatally and for which routine therapeutic measures only have heretofore been available. Clinical results with some of these serum types have been highly encouraging as far as they have gone and there have even been cures of bacteremic cases in Type 3 and other higher-numbered type infections.

Lederle Laboratories now announce rabbit sera for Type 3, Type 6 and Type 14. Sera for additional types will follow within a few weeks in the expectation that therapeutic sera for all 32 types of pneumococcic pneumonias will become available during the winter.

Sera of effective potency in many of these higher types cannot be produced in horses. Sera for these higher types are produced in rabbits and have been successfully refined and concentrated as much as ten times. This permits dosage of high unitages with reduced danger of serum reactions.

Upon the first suspicion of lobar or bronchial pneumonia the patient's sputum should be examined by the Neufeld Rapid Typing method to identify the type of pneumonia.

THE USE OF BENZYL METHYL
CARBINAMINE CARBONATE IN
THE TREATMENT OF
RHINITIS

BY H. RAY F. STICK, M.D.

A NEW drug for the symptomatic treatment
of rhinitis has recently been developed.
This preparation is a volatile ester of
benzyl methyl carbamate. The compound is
essentially odorless, non-irritating, and
possesses a rapid and marked effect on
the mucous membrane of the nose. It is
not absorbed into the system and is
eliminated by the respiratory tract.

CHILDREN

H. J. PETER, M.D. AND
J. E. COLEMAN, M.D.

The leading cause of the common
cold is rhinitis, and rhinitis is
the most common cause of the
common cold. The rhinitis of the
common cold is a temporary condition
which is caused by the irritation of
the mucous membrane of the nose.
It is characterized by a runny nose,
sneezing, and a feeling of congestion.
The treatment of rhinitis is to
relieve the irritation of the mucous
membrane. This can be done by
the use of a vasoconstrictor.
Benzedrine is a powerful vasoconstrictor
which relieves the irritation of the
mucous membrane of the nose.
It is a safe and effective remedy
for the common cold.

BENZEDRINE TARANASOL
(A Study of 3 Cases)
BY J. ALLEN FARTLEY, M.D.
PHILADELPHIA, PA.

Case 1. 3 years ago I noticed the first
attack of rhinitis. It was a very
severe attack and was accompanied
by a high fever and a runny nose.

ten of the attacks. In consequence
of the time and trouble involved
in the treatment of various types
of rhinitis, I have decided to
use Benzedrine. I have confirmed
these findings in the clinical efficacy
of Benzedrine. It was introduced
as a remedy for rhinitis and
it has been found to be a very
effective remedy for the common
cold.

Iodobismitol PROVIDES SUSTAINED BISMUTH EFFECT

Urinary excretion of bismuth after multiple injections of Iodobismitol Arrows indicate injections

It has been stated by recognized authorities that "Probably those compounds of bismuth will have the best antispirocheticidal value that are able to keep the therapeutic level of bismuth in the blood stream at such a continuous height that it will be reflected in the urine with a level of 0.003 Gm. or more of metallic bismuth per day"

The chart illustrated above shows the sustained bismuth effect which Iodobismitol provides. It is taken from a clinical study¹ which showed that Iodobismitol possesses the advantages of almost complete absorption, relatively prolonged bismuth effect at a high level and a very high efficiency with respect to therapeutic utilization of the dosage given (2 cc.)

Iodobismitol with Saligenin is a propylene glycol solution containing 6% sodium iodobismuthite, 12% sodium iodide and 4% saligenin (a local anesthetic). It presents bismuth largely in anionic (electro-negative) form. Repeated injections are well tolerated in both early and late syphilis.

SQUIBB ARSENICALS

Neoarsphenamine Squibb, Arsphenamine Squibb and Sulpharsphenamine Squibb are prepared to produce maximum therapeutic benefit. They are subjected to exacting controls to assure a high margin of safety, uniform strength, ready solubility, and high spirocheticidal activity.

THE COURT OF *Last Appeal*

THE electrocardiograph serves such an important purpose in the general practice of medicine that every physician has need for it. In the identification of disturbances of mechanism of the heart beat, it constitutes the court of last appeal. It gives vital information regarding all cardiac arrhythmias.

Simplified, inexpensive, dependable electrocardiography has been made available to the average physician with the advent of G-E's new light-weight low-priced instrument which can be used with equal satisfaction in the office or at the bedside. It is sturdy yet portable, is extremely accurate, and requires no complicated manipulation to produce a heart record that is of true diagnostic value.

Without incurring any obligation, arrange to make an electrocardiogram—yourself. It is a surprisingly simple procedure, and interest-

ing. Learn, at the same time, what a valuable adjunct it would be to your other diagnostic equipment, valuable as an investment, too. Read, sign, and mail the convenient coupon—NOW

KNOX CLINICAL NOTES

ONE OF A SERIES OF CORRESPONDENCE EXCHANGES WITH PHYSICIANS ABOUT KNOX GELATINE

QUERY about the Allergic Manifestation of KNOX GELATINE

A doctor writes, "Would you kindly tell me from what sources the materials used in making Knox Gelatine are obtained? I am especially interested in whether or not it is all beef, all pork, all sheep, or a mixture of proteins from different animals, also is the manufacture constant as to the ingredients used? This is very important to me as I want to use it for special diets in allergic cases, and for this purpose the exact sources of a food must be known and unvaried"

Knox Gelatine Laboratory REPLY

Knox Gelatine is scientifically prepared from carefully selected long, hard, shank *beef bones only*. Twenty-one control and laboratory tests are made throughout the process of its manufacture. As far as we know, no case of allergy has ever been traced to the use of Knox Gelatine. Contrariwise, there is reason to believe that when Knox Gelatine is added to milk, patients sensitive to milk will show no allergic response.

Sample and useful Dietary Booklets on Request. Write Dept 476

A GOOD EXAMPLE OF A CONCENTRATED KNOX GELATINE RECIPE

THE KNOX MILK STIR

Place the contents of 4 envelopes of Knox Gelatine in an ordinary drinking glass. Add 4 ounces of cold milk and allow to soak for five minutes. Add 2 more ounces of milk and stir until thoroughly soaked. Then place glass in small cooking kettle of hot water until gelatine milk mixture is thoroughly dissolved. Add 2 more ounces of cold milk, which will bring the temperature to a satisfactory warm drink of about body heat. A tablespoonful of prune juice or a few drops of any bland flavor like vanilla may be added.

Total 8 oz liquid—about 250 calories

Why you should insist on Knox Sparkling Gelatine

Because Knox Gelatine is 85% protein in an easily digestible form,—because it contains absolutely no sugar or other substances to cause gas or fermentation, Knox Gelatine should not be confused with factory-flavored, sugar-laden dessert powders. Knox is 100% pure USP gelatine. Knox Gelatine has been successfully used in the dietary of convalescents, anorexic, tubercular, diabetic, colitic, and aged patients.

VITAMIN-A EFFICACY

... proved in the laboratory

Carefully controlled biological tests have proved that the vitamin-A efficacy of cod liver oil is enhanced twofold when it is emulsified with Maltine. MALTINE WITH COD LIVER OIL, therefore, offers the physician not only an ideal vehicle for prescribing the vitamins A and D of cod liver oil, but also the added advantage of the valuable constituents of Maltine itself. Another feature of MALTINE WITH COD LIVER OIL is that it has none of the unpleasant oily consistency and taste usually associated with vitamin-bearing oil. This lack of taste is of particular advantage when prescribing for children.

Another preparation favored by physicians is MALTINE WITH COD LIVER OIL and IRON IODIDE, containing two grains of freshly prepared iron iodide per fluid ounce. The Maltine Company, 60 Hudson Street, New York City.

CAPSULES
of
MEAD'S OLEUM PERCOMORPHUM

Soluble gelatin capsules in boxes of 25 and 100

Not advertised to the public

IN PREGNANCY AND LOW-CALORIE DIETS and wherever vitamins A and D are required with minimum added calories

RESTRICTED diet regimens, as for the obese, know no season for vitamin therapy. Because of the frequent drain on the mother's stores and the added requirement of the fetus, the need for vitamins A and D is increased during pregnancy. Yet, it is in just such cases that there may be an aversion or intolerance to fats. In the obese, who studiously avoid butter, cream and other good sources of vitamin A, the deficiency should be made up. This can be

done in a convenient and highly acceptable manner by prescribing Mead's Capsules of Oleum Percomorphum, which combine a high potency of both vitamins A and D. Each 10-drop capsule supplies natural vitamins in amounts not less than 13,300 A units and 1,850 D units (U.S.P.). Every capsule represents more than 5 teaspoonfuls of cod liver oil* in vitamins A and D. These vitamins, moreover, are in the same ratio as in cod liver oil*.

*U.S.P. Minimum Standard

For physicians who prefer Mead's Viosterol in Halibut Liver Oil, 3-minim capsules containing not less than 8,500 vitamin A units and 1,700 vitamin D units (U.S.P.) are available.

ANNALS OF INTERNAL MEDICINE

VOLUME 11

FEBRUARY, 1938

NUMBER 8

THE IMPORTANCE OF OCULAR SIGNS IN THE DIAGNOSIS OF BRAIN TUMOR

By ERNEST SACHS, M D , *St Louis, Missouri*

ORDINARILY, when discussing the diagnosis of brain tumors, one passes in review more or less completely the whole gamut of diagnostic signs and symptoms. But in this paper I propose to select only one small part of the nervous system—the eyes—and try to show how it may be possible to localize a lesion in almost any part of the brain if the study of this part be sufficiently thorough.

The eyes should be studied from five angles

- I Ocular palsies
- II Ocular movements
- III Visual defects
- IV Ophthalmoscopic changes
- V Subjective visual disturbances

I Ocular Palsies The nerve most frequently affected by a brain tumor is the sixth nerve. This is due to the fact that it has such a very long course in the cranial cavity, and also because it may be compressed as it leaves the pons by one of the branches of the basilar artery. As the pressure on the nerve may vary from day to day, or even from hour to hour, the patient's ability to turn the eye outward will also vary. Such a sixth nerve paresis is usually unilateral. It is of no localizing value and must be considered a sign of general pressure.

On the other hand, a bilateral sixth nerve paralysis, inability to look to either side, is of great significance because in my experience it always means a lesion of the medulla where the two sixth nerves have their origin.

When the oculomotor nerve, the third, is thrown out of function, the pupil is dilated, and the eye can be moved only outward and downward. This striking picture, when it occurs suddenly, not only indicates where the lesion is but what it is, namely, an aneurysm of the internal carotid where it enters the circle of Willis. Such cases may have no other symptom.

* Read at the St. Louis meeting of the American College of Physicians, April 20, 1937

Copyright, 1938, by The American College of Physicians

than headache, the eye grounds remain normal, there is no choked disc. If, however, a third nerve paralysis develops somewhat slowly, and is combined with a choked disc, we must conclude that we are dealing with a tumor in that region, the favorite site of which is just in front of the carotid at the sphenoidal fissure. The tumors at this point have their origin from the meninges and are meningiomas, one of the most satisfactory types of brain tumor which we are called upon to treat. But mere dilatation of the pupil, without any involvement of the other muscles supplied by the third nerve, is of entirely different significance. When that happens, only the sympathetic fibers are involved. One sees this in apoplectic conditions and especially in head injuries. Such dilatation is a grave prognostic sign, and usually means a lesion, most often a hemorrhage, in or near the lateral ventricle of the same side.

II Ocular Movements The disturbances of ocular movements are the various types of nystagmus. Lateral nystagmus, when the to and fro movement is equally rapid, may be due to a congenital lesion or to multiple sclerosis, but when there is a rapid component to one side with a slower recovery, then there is a disturbance of the vestibular mechanism, and if the patient has other signs of a tumor we may be quite certain that the nystagmus is caused by an irritative lesion in one of the lateral lobes of the cerebellum,—in the right lobe if the nystagmus is more marked to the right, and in the left lobe if it is more to the left.

Vertical nystagmus is a very different affair. Not only is it produced in quite a different way but it is of considerable prognostic value, which cannot be said of lateral nystagmus. It is a much graver sign than lateral nystagmus because it is produced by an *irritative* lesion far forward in the posterior cranial fossa and is evidence that the lesion, almost invariably a tumor, is pressing upon the corpora quadrigemina. These tumors lie in the median line in the fourth ventricle, and usually are medulloblastomas which are very radio-sensitive. But if a patient is unable to turn his eyes upward, we may be sure that we are dealing with a *destructive* lesion of the corpora quadrigemina and not an irritative lesion of that area. Such lesions, some of them pineal tumors, usually lie in the posterior portion of the third ventricle which but a few years ago was a "noli me tangere" for the neurological surgeon. Today, however, in every large neurosurgical clinic, a number of such tumors have been successfully removed.

As a rule, the absence of a symptom is not of diagnostic value, yet the absence of nystagmus may at times be of very great significance. If a patient presents all the cardinal symptoms of a cerebellar lesion, but has no nystagmus, it means either that the lesion is on the surface of the lateral lobe of the cerebellum and has not involved the nuclei of the cerebellum, or that the lesion is in the region of the middle lobe, the vermis, well away from the lateral cerebellar nuclei which control the lateral eye movements.

I shall merely mention in passing the conjugate movement of the eyes

to one side, which is sometimes confused with nystagmus, but which has its origin in a center in the frontal lobe, and the mistaking of cerebellar tumors for frontal lobe tumors in the past was probably due in part to the misinterpretation of this symptom

I cannot leave this phase of the subject without drawing attention to unilateral exophthalmos, caused by a meningioma growing from the olfactory groove, which occurs often without any other signs of an intracranial tumor and occasionally in orbito-ethmoidal osteomata. Nor can I omit mention of that extraordinary phenomenon, pulsating exophthalmos, due either to an arteriovenous aneurysm or to a vascular tumor behind the orbit

III Visual Defects The optic nerves and their cerebral connections extend from the under surface of the brain in the anterior fossa to the posterior portion of the middle fossa. Lesions in the course of the visual pathway may produce different kinds of field defects, and by these field defects alone it may be possible to locate a lesion quite accurately. These defects may consist of scotomata, central or paracentral, partial or complete bitemporal hemianopsia, partial or complete homonymous hemianopsia.

A lesion that presses directly on the optic nerve may produce a primary optic atrophy and associated with this a central or paracentral scotoma. A lesion in the orbit or an intracranial lesion in the anterior fossa in front of the chiasm may produce unilateral optic atrophy. If the process has been present for a long time, the patient may lose the sight of one eye completely. We have seen this a number of times in tumors of the pituitary gland. In the series of 78 cases of pituitary tumors and suprasellar cysts which we have operated upon, blindness in one eye occurred 28 times, 18 times in the pituitary tumor cases and 10 times in the cases of suprasellar cysts. There may also be unilateral blindness caused by primary optic atrophy associated with a choked disc in the opposite eye,—that interesting but rather rare syndrome described by Foster Kennedy. This means that there is a lesion on the under surface of the frontal lobe on the side of the optic atrophy. The tumor pressing directly on the nerve causes the atrophy and by causing increased intracranial pressure produces a choked disc in the opposite eye. The eye disturbance associated with a pituitary tumor is practically always a primary optic atrophy. Only in those very rare cases in which a pituitary tumor perforates the dural envelope which roofs the sella turcica, and hence becomes intradural, does one see a choked disc. This has occurred only once or twice in our series.

The characteristic field defect produced by a pituitary tumor is bitemporal hemianopsia and this is unaccompanied by choked disc. In an early case, the bitemporal defect may be detected only in the color fields. A pituitary tumor, however, may grow out to one side and then produce an homonymous hemianopsia. Such a field defect is indistinguishable from that produced by an occipital lobe lesion, but if the tumor is in the occipital

lobe there will almost certainly be double choked disc, while the pituitary case will have only a primary optic atrophy and characteristic roentgen-ray changes in the sella

I have seen a few cases of hemorrhage into the occipital lobe, apoplexy of the occipital lobe, in which there was no choked disc, but in these cases the history of a sudden vascular insult will enable one to make the differential diagnosis

Some of the visual fibers, as they pass back toward the cuneus of the occipital lobe, make a loop in the temporal lobe, those fibers which pass to the outer side of the inferior horn of the lateral ventricle control vision in the upper outer quadrant, while those which pass to the mesial side of the ventricle control the lower outer quadrant. The nearer the lesion lies to the occipital lobe, the more nearly complete is the homonymous hemianopsia but the macular, or central vision, in an occipital lobe lesion is spared because the macula is bilaterally represented

The right temporal lobe, in a right-hand individual, was until recently considered a silent area of the brain, but these partial homonymous defects are so definite and so characteristic that they alone enable one to localize a lesion in the temporal lobe

To recognize these different types of field defects, it is essential that the examination be carried out with great care. A careless or hastily made perimetric study will not reveal such slight defects and vision must be tested every 15 degrees in order to detect these changes

Patients with such homonymous field defects often have peculiar subjective visual disturbances—hallucinations. The character of these hallucinations frequently will enable one to differentiate a temporal from an occipital lobe lesion

IV Ophthalmoscopic Changes The ophthalmoscopic study of the eye grounds is another aspect of the ocular mechanism that yields invaluable information. There are two general types of changes that one may observe. First, primary optic atrophy, and second, choked disc or papilledema

An intracranial, intradural tumor never causes bilateral primary optic atrophy. Consequently, we may conclude that if a patient has other evidence of an intracranial lesion and bilateral primary optic atrophy, the lesion must be extradural. The only intracranial lesions that produce this picture are situated around the chiasm. Most frequently these are pituitary tumors, aneurysms of the internal carotid, or an inflammatory process in that region. But of course it does not follow that because a patient has a primary optic atrophy the lesion is necessarily intracranial, for lesions in the orbit may also cause such atrophy. Since a variety of extracranial causes may produce such a picture, other diagnostic signs have to be taken into consideration before arriving at a final diagnosis

Choked disc is always due to increased intradural pressure. In the vast majority of cases the pathological lesion is a brain tumor and in these

cases the appearance of the choked disc offers many points of interest. First of all we must ask, can a choked disc be of any localizing value? It has been claimed that unilateral choked disc indicates the side on which the lesion is located. In my experience this is rarely the case, and unilateral choked disc, therefore, is of very little localizing value. Nor are the number of diopters of swelling of much importance. What we must be interested in is the age of the process, and this is best judged by the changes, histological in character, seen with the ophthalmoscope. The character of the hemorrhages, whether recent or old, and the presence of exudate, which is evidence that new tissue is being laid down in the retina, are the points to be looked for. The diopters of swelling, on the other hand, are merely evidence of the amount of edema, and this fluctuates so readily that it is of far less importance than the other changes.

The appearance of secondary optic atrophy in a choked disc is of great prognostic importance and with experience it is possible to recognize optic atrophy while a choked disc is still present. If optic atrophy is well advanced, the vision may continue to fail even if the choked disc has been relieved by the removal of a tumor, a patient may even go on to blindness in such a case.

The question has been raised, can a patient who is blind as a result of a choked disc ever regain any vision? I have never seen a patient, who has been blind even a brief time as a result of a choked disc, regain his vision, but I have seen several patients, blind because of a primary optic atrophy due to a pituitary tumor, regain normal vision. This I confess is difficult to explain, but I have assumed in such cases that we were dealing with a physiological block of the nerve.

There are a number of conditions which resemble a choked disc so closely that they are difficult to tell apart, and at times indistinguishable. In malignant hypertension, polycythemia, and true optic neuritis due to an inflammatory process, the picture is very similar. Even albuminuric retinitis at times may very closely resemble a choked disc. At times it may be possible to tell these apart only by considering other aspects of the clinical picture. In this connection I should like to emphasize that there still are points about the mechanism of choked disc that are not fully understood. There is some evidence indicating that the same mechanism may be producing the eye ground changes in several of these conditions. If this should prove to be correct, there would no longer be any justification for applying different names to these various eye ground conditions.

V Subjective Visual Disturbances The final group of visual disturbances which I want to refer to are the subjective ones. These are in the nature of hallucinations and may be grouped under two general headings—the hallucinations of form and those of color. An irritative lesion of a cortical center gives rise to these subjective sensations. The visual phenomena are different, depending upon the portion of the cortex that is in-

volved. As a rule, irritation of the visual center in the occipital lobe gives rise to hallucinations of color. The patient sees these colors in a certain portion of the perimetric field. Thus, for example, if the lesion is located in the right occipital lobe, the patient will see these colors in the left half of each visual field, since the right occipital lobe controls the vision in the right half of each retina. These colors are often described by the patient as coming from one side. In a right occipital lobe lesion they would therefore appear from the left side.

In a certain number of lesions of the temporal lobe, patients may have visual hallucinations of form. They may see peculiar things or persons. Individuals may appear deformed, they may see strange people or animals. Many of these hallucinations are very similar to those described by patients in delirium tremens, and it may be that alcohol affects the temporal lobe particularly, producing such symptoms. At times these visual disturbances may be very complicated. I recall one patient, a very intelligent school teacher, who always saw an Elizabethan pageant pass before her. She saw all this so vividly that she was able to describe the costumes accurately. This type of visual hallucination is closely allied, if not a part of, the irritative lesions produced in the temporal lobe, which were first described by Hughlings Jackson, and called by him "dreamy states." In these attacks the patient not only may see peculiar things but often also may hear strange voices, with all this he has a sense of unreality, not knowing where he is, and often forgetting his own identity.

These two types of visual hallucinations may constitute the auras preceding a Jacksonian convulsion. Associated with these visual disturbances there may often be field defects, and such a combination—visual aura, Jacksonian convulsion, and field defect—constitutes ample evidence on which to localize a lesion in the temporal or occipital lobe.

In trying to determine the location of a brain tumor, numerous methods need to be employed, but I have attempted only to point out the great importance of ocular signs and the significant rôle they play in the diagnosis of brain tumor.

THYROID ACTIVITY IN CHRONIC ARTHRITIS *

By WILLIAM B RAWLS, M D , F A C P , ANTHONY A RESSA, M D ,
BENJAMIN GRUSKIN, M D , and ABRAHAM S GORDON, M D ,
New York, N Y

OPINIONS differ as to the relationship between thyroid activity, as determined by the basal metabolic rate, and variations in the arthritic syndrome

The increased incidence of arthritis in women, particularly near the menopause, and the association of myxedema and hypothyroidism with chronic arthritis have suggested to many that a deficient thyroid secretion might be a contributing factor in the production of arthritis. Pemberton and Tompkins¹ studied the basal metabolism of 29 cases and found the basal metabolic rate (B M R) within normal limits (between plus and minus 10) in 80 per cent, the remainder being below normal. Cecil, Barr and DuBois² studied four patients with chronic arthritis in a calorimeter and concluded that there was no disturbance of metabolism. Boothby and Sandiford^{3,4} found the B M R between plus and minus 15 in 93 per cent of 69 patients with chronic arthritis. In 115 cases studied by Hench⁵ the B M R was normal in 80 per cent. Swaim^{6,7} reported a total of 312 cases. The B M R was normal in 61 per cent, below normal in 25 per cent (below 0 in 63 per cent), and above normal in 14 per cent. He concluded that "abnormal metabolism with a tendency to a minus rate is characteristic of arthritis, especially in early years, having a tendency to return to normal as the duration of the disease lengthens". Hall and Monroe⁸ reported that, in 214 cases of which 106 were rheumatoid and 108 osteoarthritis, the B M R was normal in 48 per cent and below normal in 43 per cent. However, the B M R was below 0 in 75 per cent of the cases. Hence it would appear from the latter reports that the B M R falls within accepted normal limits in the majority of patients with chronic arthritis, although most of the rates are below 0.

Hall and Monroe⁸ have discussed the literature on the relation of endocrine dysfunction to arthritis.

The present study was undertaken to determine particularly (a) the frequency distribution of the B M R in patients with chronic arthritis, (b) whether any particular range of B M R is characteristic of any one type of arthritis, (c) the relation between the B M R and disease activity, as indicated by the sedimentation rate and non-filament cell count, (d) the relation between the duration of the disease and the B M R, and (e) the effect of the administration of thyroid extract upon the course of the disease.

A total of 684 B M R determinations was made on 400 patients se-

From the Arthritis Clinic of the New York Polyclinic Medical School and Hospital, New York, N Y

lected without discrimination on admission to the clinic. In those cases in which the results were checked, the lowest figure was considered correct.

The relationship between the B M R and activity of the disease was studied by making serial tests during the course of treatment. The sedimentation rate and non-filament cell count were done simultaneously with the B M R determination. Rates between plus and minus 10 were considered normal.

TABLE I
Distribution of Basal Metabolic Rates in 400 Patients with Chronic Arthritis

| Type of arthritis | Sex | Number of cases | Basal metabolic rates | | | | | | | |
|-------------------|-----|-----------------|-----------------------|--------------------|--------------------|------------------|------------------|--------------------|--------------------|--------------------|
| | | | % +31 to +40 | % +21 to +30 | % +11 to +20 | % 0 to +10 | % 0 to -10 | % -11 to -20 | % -21 to -30 | % -31 to -40 |
| Rheumatoid | M | 48 | | 2.1 | 8.3 | 16.7 | 29.2 | 37.5 | 6.2 | |
| | F | 93 | 6.4 | 8.6 | 14.0 | 25.7 | 30.0 | 10.8 | 4.3 | |
| Mixed | M | 32 | | 6.0 | 3.1 | 6.0 | 59.5 | 21.9 | 3.1 | |
| | F | 111 | 0.9 | 0.9 | 13.5 | 29.8 | 32.5 | 15.2 | 6.3 | 0.9 |
| Osteo | M | 42 | | 2.4 | 9.5 | 14.6 | 45.3 | 19.0 | 9.5 | |
| | F | 74 | | 5.4 | 8.1 | 33.8 | 28.7 | 17.6 | 2.7 | 2.7 |

FREQUENCY DISTRIBUTION OF BASAL METABOLIC RATES

Table 1 shows the distribution of B M R in the different types of arthritis. The rates were normal in 59 per cent, below normal in 24.3 per cent (below 0 in 58 per cent), and above normal in 16.7 per cent of all cases, which agrees with the proportions found by Swaim^{6,7}. The distribution of B M R was essentially similar in the different types of arthritis, except that there were more cases with B M R above normal in the rheumatoid group.

In 141 patients with rheumatoid arthritis, the B M R was above normal in 22.6 per cent, normal in 52.5 per cent, and below normal in 24.9 per cent.

In 143 patients with mixed arthritis, the B M R was above normal in 13.2 per cent, normal in 63.8 per cent, and below normal in 23.0 per cent.

In 116 patients with osteo-arthritis, the B M R was above normal in 12.0 per cent, normal in 63.0 per cent, and below normal in 25.0 per cent.

RELATION BETWEEN THE BASAL METABOLIC RATE AND ACTIVITY AND DURATION OF THE DISEASE

In table 2, the mean sedimentation rate (Westergren method), non-filament cell count, and duration of the disease in months are arranged ac-

TABLE II

Comparison of the Basal Metabolic Rate with the Sedimentation Rate, Non Filament Cell Count and Duration of the Arthritic Disease

| Findings compared | Type of arthritis | Basal metabolic rate | | | | | | | | | |
|------------------------------------|-------------------|----------------------|------------|------------|----------|----------|------------|------------|------------|--------------------|--------------------|
| | | +31 to +40 | +21 to +30 | +11 to +20 | 0 to +10 | 0 to -10 | -11 to -20 | -21 to -30 | -31 to -40 | Mean +10 and above | Mean -10 and below |
| Number of tests | Rheumatoid | 7 | 14 | 25 | 50 | 66 | 38 | 10 | | | |
| | Mixed | 1 | 4 | 26 | 50 | 75 | 34 | 8 | | | |
| | Osteo | | 5 | 11 | 34 | 43 | 22 | 6 | 2 | | |
| Mean duration of disease in months | Rheumatoid | 43 | 60 | 53 | 41 | 44 | 54 | 43 | | 55.4 | 49.7 |
| | Mixed | 17 | 88 | 10 | 64 | 91 | 76 | 103 | | 93.9 | 76.4 |
| | Osteo | | 69 | 64 | 44 | 44 | 77 | 37 | 69 | 65.7 | 57.3 |
| Mean sedimentation rate | Rheumatoid | 30 | 35 | 34 | 25 | 28 | 23 | 17 | | 33.8 | 19.9 |
| | Mixed | 38 | 10 | 22 | 19 | 24 | 19 | 15 | | 23.0 | 16.7 |
| | Osteo | | 7 | 9 | 19 | 23 | 21 | 10 | 14 | 14.4 | 11.2 |
| Mean non-filament cell count | Rheumatoid | 21 | 23 | 18 | 15 | 18 | 14 | 11 | | 19.0 | 13.3 |
| | Mixed | 9 | 11 | 16 | 14 | 24 | 13 | 13 | | 14.8 | 12.7 |
| | Osteo | | 10 | 15 | 15 | 17 | 15 | 11 | 16 | 13.5 | 11.7 |

according to the type of arthritis and the B M R. On the basis of 527 tests made on 341 patients, the following relationships were found. The sedimentation rate, non-filament cell count and duration of disease were higher in all groups with basal metabolic rates above normal. This was particularly true of patients with rheumatoid arthritis, the mean sedimentation rate being 33.8 mm in the above normal group and 19.9 mm in the below normal group and the mean non-filament cell count being 19.0 in the above normal group and 13.3 in the below normal group.

EFFECT OF THE ADMINISTRATION OF THYROID EXTRACT

Thyroid extract (Lilly) was administered to a number of patients with chronic arthritis, with the following results. Only 20 per cent of patients with markedly active rheumatoid arthritis showed improvement. Many patients could tolerate only small doses and, in some instances, it was necessary to discontinue it. In other patients there was increased resistance to intercurrent infection, the appetite improved and there was a sense of well-being. However, both the joint symptoms and the B M R remained unaffected in these cases, even though the latter was below normal.

A number of patients who had shown marked hypersensitivity to vaccine tolerated larger doses and the arthritis improved when thyroid extract was also given. Patients who did not respond to thyroid extract alone improved when given vaccine also. Thus thyroid extract is a valuable adjunct in some cases, but it does not always bring about improvement when used alone.

About 41 per cent of patients with mixed and osteo-arthritis improved

following the administration of thyroid extract. This was particularly true in those cases involving the knee joints. Overweight women with large, swollen, tender, painful, stiff knees often had excellent results, particularly in reduction of swelling, increased motion and lessened pain. When the fingers were involved, marked improvement was often noted, particularly in early cases. Osteo-arthritis of the hip, spine or shoulders did not respond to the administration of thyroid extract, but good results frequently followed its use in inactive cases of the Marie Strumpell type of arthritis. The B M R frequently became normal in patients with mixed and osteo-arthritis, but rheumatoid types were influenced only infrequently.

DISCUSSION

The results obtained in the 400 cases reported in this paper confirm the reports of previous workers, that the basal metabolic rate is below 0 in 55 to 80 per cent of patients with chronic arthritis.

The smaller number of B M R below normal in the present series of cases as compared with those reported by Hall and Monroe⁸ may be explained, as they pointed out, by several factors. For example, ambulatory patients, such as those studied in the present series, have higher B M R than hospital patients. Further, constant pain, causing insufficient rest and sleep, increased nervousness, etc., all tend to increase the B M R. This lends support to the contention of Hall and Monroe⁸ that the calculated B M R in these patients is always higher than the true rate. Assuming that the calculated rates were about 10 per cent too high, and adjusting the observed rates by this correction, 82 per cent of the patients in the present series will be found to have a B M R below 0.

Poor nutrition of the joint has long been considered a causative factor in hypertrophic arthritis and, for that reason, this type of arthritis has been referred to as "degenerative" or "senile." The occurrence of several signs of hypothyroidism in patients with osteo-arthritis led Hall and Monroe⁸ to believe that a lack of thyroid secretion was a factor in the etiology of these cases. Swain⁶ suggested that a low B M R may precede arthritis. It is quite possible that a decreased secretion of thyroid hormone may affect the nutrition of the joints. Osteo-arthritis may also result from long-continued inadequate repair of traumatized joints. This theory is supported by the fact that joints, such as those of the hips, spine, knees and fingers, which are subject to considerable mechanical stress and strain are most frequently involved in hypertrophic arthritis. However, this theory may not apply to rheumatoid arthritis, in which case infection probably plays a prominent rôle and lowered metabolism is only one of a long chain of effects.

The B M R is increased in the active stage of early rheumatoid arthritis, but is reduced when the disease becomes chronic, even though signs of active infection may still persist. As the disease becomes less active and ankylosis begins to develop, the B M R tends to return to normal.

In the chronic stage, the brunt of the toxemia falls upon the liver, producing symptoms of intoxication of that organ in addition to those already affecting the thyroid. Usually there is also anemia, loss of weight, nervousness, emotional instability, rapid pulse, poor appetite, etc. In studies made in this clinic,⁹ 73 per cent of such patients had liver dysfunction as judged by the Azorubin S appearance time. We⁹ have confirmed Davis'¹⁰ findings that the majority of these patients have lowered serum proteins and a reversal of the serum albumin-globulin ratio. The B M R was below normal in 90 per cent of patients with abnormal Azorubin S appearance times and altered albumin-globulin ratios.

In the ankylosing stage the improved B M R can be explained by lessened toxemia which permits the liver and thyroid to return to normal function. It is characterized by the disappearance of nervousness, irritability, poor appetite and depression. The color improves and the patient assumes a more cheerful attitude. This change is so noticeable that, when it does occur, it reminds one of the crisis in pneumonia. The rate of appearance of the three stages varies considerably with different patients. Sometimes the ankylosing stage is reached in a few months, while in other cases it requires several years.

The sequence of lowered B M R, abnormal Azorubin S appearance time, and alteration of the serum albumin-globulin ratio although not always occurring in this order, appear to be additional progressive effects of the infection in rheumatoid arthritis and must be corrected to obtain best therapeutic results.

In rheumatoid arthritis it is difficult to influence a low B M R. On the other hand, in a large number of patients with mixed and osteo-arthritis, the B M R can be increased with thyroid extract. Its value in these cases is as an adjunct to other forms of treatment and it should never be considered as an adequate remedy by itself. Successful thyroid medication is characterized by reduced nervousness, fatigue and depression, improved appetite and sleep, and by other signs of constitutional improvement.

CONCLUSIONS

1 The basal metabolic rate was within normal limits in 59 per cent, below normal in 24.3 per cent, and above normal in 16.7 per cent of 400 patients with chronic arthritis.

2 The number of cases showing basal metabolic rates below normal was essentially similar in the rheumatoid, the mixed arthritic and osteo-arthritic cases. However, in the rheumatoid group more cases showed rates above normal than in the other two groups.

3 In patients with mixed and rheumatoid arthritis, the basal metabolic rate varied with the activity of the disease.

4 The duration of the disease was greater in those patients with a basal metabolic rate above normal than in those with normal or sub-normal rates.

5 Small doses of thyroid extract, although not curative per se, frequently produced some improvement in joint symptoms and raised the general resistance

6 Thyroid extract is more effective in the mixed form of arthritis and in osteo-arthritis than in rheumatoid arthritis

The authors wish to thank George H Chapman for his advice and help in the preparation of the manuscript

PLASMAPHERESIS EXPERIMENTS UPON THE INFLUENCE OF COLLOID OSMOTIC PRESSURE, WATER AND SALT IN EDEMA FORMATION

By ARTHUR C KERKHOFF, B S , Ph D , M D , *Minneapolis, Minnesota*

NUMEROUS investigators have produced edema by a reduction of the plasma proteins. The reduction of the plasma proteins by repeated bleedings is called plasmapheresis. Leiter^{1,2} and Barker and Kirk³ were the first to carry on this work. Since that time numerous investigators, chiefly Shelburne and Egloff,⁴ Lepore,⁵ Darrow, Hopper and Carey,⁶ Weech, Snelling and Goettsch,⁷ Kylin⁸ and ourselves^{9,10} have carried on these experiments. Our method of plasmapheresis has been essentially the following. Five to eight hundred cubic centimeters of normal blood were obtained from the right or left ventricle of a normal dog. This blood was citrated, centrifuged, the plasma thrown away and the cells, after having been washed several times with Ringer's solution, were suspended in Ringer's solution in an amount sufficient to bring them to the original volume. The dog whose proteins were to be lowered was then placed on the table, a right heart puncture was done, and 500 to 800 c c of blood were removed depending upon the size of the dog. The cells of the first dog suspended in the Ringer's solution were then injected into the jugular vein of the second dog. The blood removed from the second dog was then centrifuged and the cells washed and suspended in Ringer's solution up to the original volume for the purpose of future reinjection. Reinjection of red cells in plasmapheresis experiments is necessary in order that anoxemia be excluded as a factor in edema formation. This process was repeated several times a day, depending upon the type of experiment. The dogs were allowed to drink as much water as they desired during the course of the experiment and were given previously determined amounts of either saline or water by stomach tube at each bleeding. A record was kept of the weight of the dog, the amount of blood removed, the amount of fluid intake, the amount of fluid output, the plasma protein level, the osmotic pressure of the plasma colloids, and the amount of edema. When we first undertook plasmapheresis for the purpose of developing edema in dogs, we decided to give only water by mouth, using no saline. Both Leiter, and Barker and Kirk, gave large daily amounts of saline to their dogs during the time they were attempting to produce edema. We thought that such large amounts of salt would have some effect on the amount of edema produced because correspondingly large doses of salt given to

* Received for publication March 29, 1937

From the Department of Medicine, University of Minnesota, at the Minneapolis General Hospital

a nephrotic patient would be sufficient to bring on massive edema. Therefore in our first experiments we gave the dogs only water. We carried on several experiments under these conditions and were disappointed to find that we could not produce a marked edema. Despite the fact that we reduced the blood proteins to levels far below those at which Leiter, and Barker and Kirk obtained edema and despite the fact that the osmotic pressure of the plasma colloids was far below that of the usual nephrotic patient with edema, only a tendency to edema was produced. Slight edema would be formed quite readily whenever some other factor such as the application of straps about the legs or injury to a vein through frequent puncture produced an increase in venous pressure. In one such experiment (table 1) which lasted over a period of 13 days, the dog was given 14,500 c c of water and put out 13,730 c c of urine. The colloid osmotic pressure was reduced to values of 5.6 to 6.9 mm Hg*. At autopsy the dog showed practically no edema. Having failed to obtain any considerable amounts of edema by this method, we decided to repeat the experiment, using saline instead of water. In one such experiment (table 2) which lasted over a period of five days, the dog was given 7425 c c of saline and urinated only 3820 c c. He developed marked ascites and anasarca. A comparison of the two tables shows that the colloid osmotic pressure was reduced to approximately the same level in both experiments. Yet in the experiment where saline was given instead of water, the dog developed massive edema.

These experiments, of course, lead us to certain definite conclusions, namely, that salt is necessary in the formation of edema and that without salt, even though the colloid osmotic pressure be reduced to very low levels, only little if any edema can result (unless other factors such as a rise in venous and capillary pressures develop at the same time). We then attempted to produce edema in a 24 hour period by repeated bleedings during the day. Table 3 gives the results of such an experiment. Five thousand six hundred cubic centimeters of blood were removed by repeated bleedings and replaced with red cells and Ringer's solution in a 24 hour period. The dog was given 4760 c c of fluid and put out 940 c c of urine. We also made an attempt to study the salt intake and output on this dog. It was found that he took in 30 gm of salt during this period and put out 9.25 gm in the urine. In other words, there was a retention of 5.5 grams of salt per liter of water. This dog had marked edema at death. There were 500 c c of ascitic fluid and the tissues of the neck and legs showed free fluid on section.

Having demonstrated that it was possible to produce edema by reduction of plasma proteins in a 24 hour experiment, we decided to attempt the following type of experiment (table 4). Instead of suspending the cells in Ringer's solution before reinjecting them, we suspended them in 6 per cent gum acacia solution. The experiment was carried out in exactly

* Normal for the dog is 18.6 mm Hg

| 2-16-33 12 30 a m | 32 | 800 cc | 200 cc Ringer's intravenously 500 cc saline orally 1000 cc H ₂ O taken | None | | 1.68 4.5 | | | |
| 2-16-33 8 30 a m | 34 | 800 cc | 100 cc Ringer's intravenously 100 cc 30% acacia intravenously 500 cc saline orally | 440 cc | 1012 | .84 4.5 | 2.12 | Present | At 8 30 a m Total protein 2.56% |
| 2-16-36 4 30 p m Dog died | | Totals | 250 cc H ₂ O 4760 cc | 940 cc | | Total 30.06 gm | Total 9.27 gm | Marked | |

Dog had 500 cc of ascites at death. Tissues showed free fluid in neck and legs on cutting into them.
Autopsy also showed 150 cc of bloody pericardial fluid.

TABLE IV

In this experiment, plasmapheresis was carried on as follows. The blood was centrifuged, the plasma discarded and the cells were made up to the original volume with 6 per cent gum acacia in Ringer's solution

| Date | Weight | Blood exchanged | Fluid given c c | Fluid recovered c c | NaCl given gm | NaCl recovered in urine | Plasma proteins | Colloid osmotic pressure mm Hg | Edema |
|------------------|----------|-----------------|---|------------------------|-------------------|----------------------------|--------------------------|-----------------------------------|-----------------|
| 2-23-33 9 a m | 19.5 | 700 c c | 200 c c Ringer's intravenously 400 c c saline orally | | 1.68 gm 3.6 gm | | After bleeding 0.97% | | None |
| 2-23-33 2 p m | 21.5 | 700 c c | 200 c c Ringer's intravenously 400 c c saline orally | | 1.68 gm 3.6 gm | | Before bleeding 2.1% | | None |
| 2-23-33 7 p m | | 700 c c | 200 c c Ringer's intravenously 400 c c saline orally | | 1.68 gm 3.6 gm | | Before bleeding 1.12% | | None |
| 2-24-33 1 a m | 21.0 | 700 c c | 200 c c Ringer's intravenously 770 c c H ₂ O orally | 2100 | 1.68 gm 3.6 gm | | Before bleeding 0.97% | 15 mm Hg | None |
| 2-24-33 | Dog died | | 120 c c H ₂ O | 480 | | 20.07 | | | None at autopsy |
| | | Totals | 3290 c c | 2590 c c | 21.1 gm | 20.07 gm | | | |

9.3 gm of gum acacia were recovered in the urine
Autopsy showed no edema—no ascites—veins were markedly distended

TABLE V

In this dog no plasmapheresis was performed but he was given water and salt in the same amounts as were the dogs on which plasmapheresis was done

| Date | Weight | Blood exchanged | Fluid given c c | Fluid recovered c c | NaCl given | NaCl recovered in urine | Edema |
|----------------------|--------|-----------------|---|-------------------------------|--------------------|-----------------------------|-------|
| 3-20-33 10 40 a m | 17.5 | None | 400 c c saline orally | | 3.6 gm | | None |
| 3-20-33 1 p m | 18.5 | None | 300 c c Ringer's intravenously 400 c c saline orally | | 2.52 gm 3.6 gm | | None |
| 3-20-33 5 30 p m | | None | 300 c c Ringer's intravenously 400 c c saline orally | | 2.52 gm 3.6 gm | | None |
| 3-20-33 Midnight | | None | 200 c c Ringer's intravenously 400 c c saline orally | | 1.68 gm 3.6 gm | | None |
| 3-21-33 | 16.5 | | Water intake 100 c c Total fluid 2500 c c | 2400 Total output 2400 c c | Total NaCl 21.1 gm | Total NaCl in urine 19.9 gm | None |

At the end of the experiment, there was no demonstrable edema

the same manner as the previous experiment except for the addition of gum acacia. The blood proteins were reduced to levels far lower than those necessary to produce edema in any of our other experiments. However, in this experiment the colloid osmotic pressure of the plasma was at nearly the normal level for dogs. Under these conditions the dog was given 21 gm of salt and excreted 20 gm of salt. At autopsy there was no edema, the tissues were dry, and there was no ascites. It then became necessary to ascertain how a normal dog without any plasmapheresis would handle the same amount of water and salt. Accordingly, the experiment shown in table 5 was undertaken. In 24 hours the dog was given 2500 cc of fluid, mostly saline and Ringer's, and put out 2400 cc of urine. He took in 21 gm of salt and excreted 20 gm of salt. No edema was formed.

These experiments prove conclusively that the maintenance of the colloid osmotic pressure at the normal level by some inert colloid (gum acacia) is

TABLE VI
Summary of Experiments on Plasmapheresis in the Production of Experimental Edema

| Types of Experiments | Plasma proteins | Colloid osmotic pressure | Excess salt | Edema |
|---|-----------------|--------------------------|-------------|--------|
| Plasmapheresis Dog drinking only water | Reduced | Reduced | Absent | None |
| Plasmapheresis Dog drinking saline | Reduced | Reduced | Present | Marked |
| Plasmapheresis replacing plasma with 6% gum acacia Dog drinking saline | Reduced | Normal | Present | None |
| No plasmapheresis Dog drinking saline | Normal | Normal | Present | None |

This table shows that two factors are necessary in the production of experimental edema, namely reduction of the colloid osmotic pressure and adequate salt intake.

sufficient to stop any tendency to edema formation. Even when the protein levels were reduced to values far below the level at which edema usually appears in such an experiment when no gum acacia is given, no edema developed. These experiments prove conclusively that the tendency to edema formation is a function of the colloid osmotic pressure of the plasma and would tend to show that one of the main functions of proteins in the plasma is the maintenance of a normal colloid osmotic pressure. Table 6 summarizes the experiments on plasmapheresis and shows the effect of various factors in edema formation.

CONCLUSIONS

1. Plasmapheresis experiments on a dog in which the colloid osmotic pressure of the plasma is reduced to levels equal to or below those which

cause edema in man will not lead to edema formation or salt retention as long as the dog is given only water and a very much restricted intake of salt

2 The same experiment leads to marked edema formation and salt retention when the dog is given normal saline instead of water

3 Twenty-four hour plasmapheresis experiments in which the proteins are reduced to a very low level within 24 hours result in marked edema within this short period of time if the dog is given saline to drink

4 Dogs in which plasmapheresis has reduced the protein level below the usual edema-forming level but in which the colloid osmotic pressure of the plasma has been maintained by an indifferent colloid, gum acacia, develop no edema or salt retention

5 Normal dogs given large amounts of saline by stomach tube retain no water or salt

6 Retention of salt is due to filtration of protein-free plasma as edema Normally functioning kidneys will not excrete salt if it is prerenally deviated as edema by ultrafiltration in the capillaries

THE DOCTOR HIMSELF AS A THERAPEUTIC AGENT^{*}

By W R HOUSTON, F A C P, *Austin, Texas*

IN recent years there has been increasing talk about the broader aspects of medical service. Medical men themselves have been anxiously considering not merely the building stones of medicine, but the plan of the entire medical structure. A great foundation has recently asked us for a free expression of opinion concerning American medicine. We are asked how well is medicine fulfilling its function to society, how can the benefits of medical science be best distributed, how shall medicine best be meshed with the economic structure? And these questions have led to further questioning as to the values that we have for distribution. We have considered not only the question of whether the conduits for conveyance of medical service are open, but also the purity of the sources of supply. From all this free and even voluble outpouring of opinion, it has come to light that despite there being many expressions of opinion that are merely slogan-mongering, expressions with more than a tinge of trade-unionism in them, there is also emergent much well-considered thought, the thought of informed and able men.

In all this discussion there has constantly echoed one recurring phrase, a phrase which it is my purpose to consider here, a phrase that has sometimes been thought to have grown so threadbare that it has been designated as merely a "smoke-screen" to conceal some unavowed purpose, the phrase, "Personal relations between doctor and patient."

Those who have most used this phrase have not been the most liberal thinkers. It has been employed rather by men who heretofore had been disposed to regard medicine as a tight, fast-set science, men accustomed to emphasize the science, rather than the art, of medicine, men who had previously looked askance on discussions of human relationship as the vapors of undisciplined thought. But now, from an unexpected quarter of the horizon, succor appears. In their anxiety to withstand change in the economic relationships of medical practice, these same men speak urgently of dangers to the relationship between doctor and patient. This relationship, which has received so little consideration in our councils, which has rarely been discussed at our medical meetings, has now become a citadel of refuge, a chief bulwark against socialization.

A recognition of the importance of the relationships between doctor and patient, even though belated, is none the less good. This relationship is indeed an overwhelming handicap to any plan for standardizing and mechanizing medical care. There are many things in medical work that can be standardized, to which methods of shop efficiency can be applied. The ap-

* Read at the St. Louis meeting of the American College of Physicians, April 19, 1937

plication of medical science to the care of swine and cattle has been best accomplished by mass standardization. The methods of pathology, immunology, clinical research and diagnosis have been brilliantly illustrated in our dealing with the domestic animals. In my State of Texas far more money is spent by the State on its veterinary service than on its public health work for human creatures, some evidence that the State is conscious that mass action is efficient in dealing with veterinary problems.

What distinguishes veterinary medicine from human medicine is just this relationship between doctor and patient. It is a relationship that has a long history. In the early history of medicine, it comprised all that the doctor had to offer the patient. It is only very recently that medicine has had more to give. A survey of medical history acquaints us with many illustrious names. Step by step these men contributed to an understanding of anatomy, physiology and to the description of clinical syndromes, but if we except such courage and consolation as the physician might offer, they had very little to give by which the patient could profit. Historians sentimentalize the practical values of ancient medicine. One scans the pages of Hippocrates in vain for any treatments of specific value. The pages of medical history read like the log of an old-fashioned ocean voyage, in which it is noted that on such a day a whale spouted, on such a day a flying fish was sighted, or a bit of driftwood, but in which no mention is made of the huge prevailing fact that what was constantly seen day by day, almost to the exclusion of other sights, was the unending green waste of water. And this inevitable circumambient ocean is, by analogy, in medical history the "personal relationship between doctor and patient."

By this it is not meant to say that doctors didn't do things for their patients. They did a great deal. The need of human beings for action when in distress, some sort of action, without much question as to whether the act was wise or foolish, was met. Medicine, as the anthropologists tell us, was originally magic. Pharmacology is a late development. Medicines were prescribed that produced an overt effect,—vomiting, sweating, purging.

In a word, the medicines used were placebos, something to please the patient. The doctor, himself, by words of cheer and comfort sought to please the patient. His medicines were merely symbols to reinforce this purpose. Perhaps I may seem to be stretching the meaning of the word, placebo. It is ordinarily taken to mean a procedure undertaken to gratify the patient's desire for active intervention, but which is understood by the doctor to be inert and useless. For example, a bogus puncture. There is, however, a second sort of placebo, which seems to be no less a placebo, in the employment of which the patient's attitude is the same, but where the doctor's attitude differs in that though the procedure is valueless, the doctor esteems it to be valuable. For example, an ovarian tablet. As to the first type of placebo little need be said. It is a type of treatment not uncommonly used, effective at times yet not held in high esteem. The second sort of placebo the type which the doctor fancies to be an effective

medicament but which later investigation proves to have been all along merit, is the banner under which a large part of the past history of medicine may be enrolled. The herbs of the Indians, the pharmacopœias of the Orient, a large part of the contents of our older books on medicine are made up of these placebos in which doctors erroneously had faith. Their usefulness was in direct proportion to the faith that the doctor had and the faith that he was able to inspire in his patients. But related to this second group of placebos is a third group, a group in which the placebo used while it is believed in by the doctor, is no longer harmless but harmful, sometimes very dangerous. It would seem peculiarly contradictory to speak of the painful and dangerous placebo, yet men are so constituted that they feel the need in dire extremity of resorting to dead measures. Nervous patients, in particular, feel that a certain standing and sanction is bestowed on their maladies when violent therapeutic measures are used.

The great lesson, then, of medical history is that the placebo has always been the norm of medical practice, that it was only occasionally and at great intervals that anything really serviceable, such as the cure of scurvy by fresh fruits, was introduced into medical practice. By and large, the doctors were, as reported by that sane and shrewd observer, Montaigne, a danger to their patients. The medical historian is apt to mislead us when he speaks of the learned and skilful doctors of the past. While undoubtedly exceptional instances might be unearthed to show that these physicians accomplished something for the somatic good of their patients, in the large view we are forced to realize that their learning was a learning in how to deal with men. Their skill was a skill in dealing with the emotions of men. They themselves were the therapeutic agents by which cures were effected. Their therapeutic procedures, whether they were merit or whether they were dangerous, were placebos, symbols by which their patients' faith and their own was sustained.

The history of medicine is a history of the dynamic power of the relationship between doctor and patient. Through centuries when doctors were doing more harm than good this dynamic force has sustained the medical profession in the esteem of their clientele, it has inspired their fellow citizens with such faith in its values that they were willing to give economic support to the doctor. However little the doctor had to offer it was to him that men turned in the distress of illness. When we observe the honor and emolument bestowed on the physician throughout the ages we are forced to exclaim, "Oh rare cogency of the relation between doctor and patient."

The scene has changed. With the name of Pasteur we associate an increasingly rapid acceleration in our emancipation from the sway of the placebo. The prestige of medicine has constantly mounted higher and higher and this prestige rests on a solid foundation. So rapid have been the acquisitions in bacteriology, immunology, in sanitation, so increasingly efficient have we become in hygiene, in dietetics, in surgery, in the executive distribution of the scientific plans through departments of health and organizations for nursing, so great has been the eagerness to acquire new knowledge

and to institute fresh researches, that we have been tempted to forget our origins, the long historical past of "personal relations between doctor and patient" Not that there are not enough reminders of it The relation between nostrum-vendors and their patients, between chiropractor and patient, between quack of whatever stripe and patient should suffice to remind us of our past The fact that States and legislatures have shown themselves so kindly disposed towards the charlatan and his placebos gives one to see how strongly entrenched in the popular mind is the precedence of the healer-patient relationship over the claims of somatic medicine No one considers applying the principles of osteopathy to pigs and steers, because osteopathy is a human relationship, a "personal relation between doctor and patient" It is not through cults that exploit personal relationship but through our knowledge of bacteriology, immunology and dietetics as embodied in veterinary science that the legislature is expecting to see swine and cattle brought sound and healthy to the slaughter pen

What is the something more, something different from the veterinary medicine that the patient expects when he goes to the doctor? It is certain that were he subjected to Socratic questioning no very clear answers could be had The patient is aware of the doctor's prestige but he is unaware of what sort of foundation it rests on Between what he expected as magic potion or compelling ritual from the doctor-priest and what he expects from scientific medicine there lies a bond of kinship For many a patient the drug prescription is still heavily tinctured with magic, for him the doctor is a medicine man, a drug-giver, and it may be regarded as an ameliorating circumstance that when such a patient strays off after a drugless cult in addition to being in revolt against common sense, he is also in revolt against outworn superstition

But what the patient most imperatively demands from the doctor is, as it always was, action However the doctor may spar for time by delays of diagnostic study, these delays only whet the patient's appetite for decisive action In a large and constantly growing number of instances the physician is able quite satisfactorily to render the service expected of him When it is a question of diabetes or myxedema, anebiasis or syphilis, beriberi or macrocytic anemia, the physician sets about his work with resolute confidence In the group of diseases for which nursing care is our chief resort, bronchial pneumonia, typhoid fever, and the rest, the line of procedure is scarcely less well-defined In situations of utterly hopeless outcome the physician at least understands that consolation and the relief of suffering is his rôle

But what of the patients who fall into none of these classes? What proportion are they of all those that seek treatment? Sydenham estimated that they comprised a sixth of all his patients Charles Emerson, in his recent book, estimates them as half, and estimates further that half the symptomatology of the somatically ill is nervous These patients are even more demanding than the somatically ill for action As a class they are

little inclined to listen to sincer reasoned counsel, however adroitly it may be worded. They are usually disposed to question the diagnosis if told they have no somatic disease. The approval of these patients is essential to the doctor's success in practice. What can he do? What he very often does is to treat them with placebos, coupling the placebo with such suggestions for improved mental hygiene, and better ways of living as he can sandwich in. If reproached for degrading the pharmacopeia to the rôle of placebo, these men retort, "Well, after all, a man has to be practical."

Often enough, doctors of little critical discrimination come to believe in the placebo just as their faith is able to impart to the patient the faith that heals, and the faith seems to be justified by its fruits. Such men argue hotly for their placebos, since it is a well-known trait of character that ire is engendered by matters of faith, not by matters of demonstration, men fight for a belief, not for a statistical deduction. These are they that loudly affirm "thou shalt have no other placebos before mine," and pursue with bitterness the alien placebo-mongers of another cult.

When thoughtfully considered, this situation is not one to be regarded with comfort. Medical men are not without misgivings about the spurious psychotherapy that they are under constant temptation to practice. Yet the path to development of a better psychotherapy is full of obstacles. The doctor's training in the laboratory and the ward has offered few opportunities for the development of any aptitude in dealing with the problems of personality. Doctors consider that their vocation is to deal with things that can be weighed and measured and that the reactions of the cerebral cortex and the autonomic nervous system are too intangible for them to deal with. As a distinguished member of this body, and contributor to this program recently wrote me

"I suppose that I am particularly bitter about the people whom we may as well call neurotics, who, as you say, take up so much of an internist's time. They are the people who drove me out of practice. I never could see any sense in paying any attention to them because, as your word picture of them so graphically shows, they have neither sense, nor gratitude, nor any idea of cooperation, nor any qualities that might endear them to man, woman or child.

"I cannot understand why those of us who have trained ourselves to take care of people who have organic disease can't be allowed to take care of organic disease. Why won't these people take our word for it that there is nothing the matter with them and let it go at that? I suppose I have as many somatic sensations as anybody on earth but I explain them to myself in a physiological way. Why can't an intelligent neurotic take the same sort of advice that I give myself? There seems to be no way of handling them except that sort of semi-quackery that some highly respectable members of our fraternity are able to get away with so successfully."

Here is a credo. There is a confession of faith. It has led a highly successful internist to give up his practice so he says, and seek other employ-

ment It is as though one said "I don't like feces," and refused to treat dysentery or cholera The brain and nervous system are organs of the body, their functioning is observed in behavior and feeling Now, when it has become a pride of medical research that we study function, when studies of the function of the heart, the kidneys, the liver, are constantly multiplied, why refuse to consider the functions of the master tissues,—the brain and vegetative nervous system? Wouldn't it be about like refusing to consider disorders of the circulation though admitting a willingness to treat another system of the body?

And yet the above statement is one of the most logical statements that could be made It is as logical as the rack and the faggot for the heretic What could be more logical—when eternal torture in hell awaits the heretic—how humane to torture him now in order to spare him endless torture The flaw in the logic is that there is no hell of eternal torture, the flaw in the logic of my correspondent is that behavior and feeling do not subsist in some separate ghostly realm but form a part of the organic activities of man The postulate that underlies my correspondent's viewpoint is physiologically untenable

And another thing—a rather base practical point to which I would like to invite you—is that my correspondent's view won't pay out Not to refer to the fact that it has driven him from the practice of medicine (he is spoofing about that), a much worse thing is it will tend to drive patients away and drive many doctors to penury In Germany this viewpoint has long existed It was expressed by the Chancellor of Washington University today when he said, "The doctor had better stick to his last" The result of this credo in Germany has been that the offices of doctors are empty while those of naturopaths overflow, that quacks abound as nowhere else, that finally the Hitler Government has set up the quack as the State Medicine The Fuhrer in medicine is a Naturopath

An even greater obstacle, however, lies in the patient himself The patient's philosophy is usually the traditional one that the mind and body are quite distinct affairs, that he has come to see the doctor about his body, and that if the doctor begins to talk about psychic matters he is being cheated There was a certain admirable unity in primitive days when the doctor-priest offered the magic potion to exorcise the demon of sickness That unity has been lost We now face a hopeless dichotomy It will be an uphill road to try to explain to the patient the unity of the organism, that mind is an aspect under which the integrated body is to be regarded, that the soul represents the interplay between the organism and its external and internal environment Any such talk the patient would regard as an evasion, as making light of his trouble, and the physician who expounds such views may find that his patient will seek another who is more in accord with his own viewpoint, and, as he will doubtless believe, possessed of a keener apprehension of the diagnostic problem

But it is time to turn from the question of difficulties and consider

the search for a possible solution to this question of how to deal with the 75 per cent of nervous symptoms which present themselves in our patients, to consider dealing with them in some more thorough-going way than through the employment of tonics and sedatives, to seek whether there may not be something more admirable than the resort to placebos. In the first place it may be asked, can nervous symptoms be studied and dealt with by the methods of the exact sciences.

I have recently read a little book, "Einfluss der Gemutsbewegungen auf den Körper." In this account of the influence of emotional disturbances on the body, I find some 16 pages of bibliography devoted chiefly to a record of experiments, most of which attempt to weigh and measure those things that we are wont to call intangible. There are innumerable experiments recording the effect of emotion, not only on heart rate and blood pressure but on the size of the heart, not only on the titer of acidity of the gastric juice and on gastric motility but on the position of the stomach, not only on the frequency and amount of urinary output but on the chemical composition of the urine, experiments that indicate the effect of emotion on blood chemistry, on electrical reactions in the skin. Much of this subject matter was finely developed in Dr Cannon's oration last year. These studies go far to show that what we have called intangible is really tangible. Emotional life does, it is true, admit of exact scientific study. From a consideration of these experiments we will indeed get many fruitful conceptions of great help in practical daily work. Physiological laboratories, however, deal as a rule with brief and elemental emotions. They have not yet arrived at the point where they can take account of these neuro-muscular dispositions that are concerned in hope and courage, in depression and loss of confidence, in the long rankling of envy or the serenity of peaceful acquiescence. Suggestive as are these studies, they do not put into our hands diagnostic instruments for the study of our nervous patients. Nor do they tell us in any unequivocal way what we must do for them.

Another solution that has in recent times been much emphasized is that the practitioner of medicine should acquire the psychiatric viewpoint. There must be a closer liaison between psychiatry and medicine. There can be no doubt that internal medicine not infrequently is biased toward an explanation of symptoms as necessarily due to structural and chemical change when the true explanation lies in a disturbance of the emotional life. Nothing would seem more logical than that the psychiatrist, through his familiarity with the gross disturbances of reaction and behavior, should bring us help in dealing with milder disturbances. As the late Dr Salmon pointed out, we cannot refuse to the study of the neuroses our active concern for the very good reason that we have accepted from the state the responsibility for the care and direction of the insane. If we accept the responsibility for the care of advanced sickness of the soul, we must all the more be attentive to an incipient sickness.

There can be no doubt that there does exist a chasm between psychiatry

and medicine. A circumstance that tends to widen the chasm is the profound reluctance of the nervous patient to be placed in the category of psychiatric patients. He insists, "I am not crazy," and resents even the suggestion that he may have symptoms that are not of somatic origin. It might be an excellent thing if all nervous patients could be cared for by skilled psychiatrists, but in many instances the very crux of the difficulty is that the patient does not consider himself a nervous patient. The battle in many cases would be nearly won if the patient could be induced to place himself in the hands of a psychiatrist, but actually the heat of the battle is over before the malady encounters its proper antagonist.

It is indeed true that the psychiatrists have contributed much to our understanding of the nervous patient, but the practitioner is likely to feel that the psychiatrist he knows is chiefly concerned with the problems of custodial care and has small opportunity to become conversant with such organic nuances, such emotional problems as are daily encountered in practice. He scarcely understands that by the psychiatric outlook is meant a consideration of the broad issues of the dynamics of personality.

If the practicing physician turns to the school psychologists for aid, his findings may prove to be even more barren. Non-medical psychologists are at a considerable disadvantage in that they do not give sufficient weight to the problems of sleep and diet, the systole and diastole of effort and repose.

One cannot advance against the disorders in the emotional sphere by mere reasoning. By the emotional sphere is meant not merely fear, rage and sex-love, but the whole inner reaction-mechanism, the reactions of single organs, of functional systems, the reactions of mood, of desire, of the inclinations and vital drives of the integrated organism. It is these great vital tendencies that the psychobiologist conceives as furnishing the motive power. Their chief seat is the thalamus, the basal ganglia, their expression is through the autonomic nervous system. The intellect, the cortex is their servant, its mission to find means for their satisfaction. If the mind is the steering wheel, the emotional life is the motor, or a better analogy, the vital tendencies dictate the direction and the goal while the mind finds the path that leads thither. It is well to seek new analogies to reinforce the truth that reason is servant, that vital tendencies as expressed in the emotional life are master.

As the patient faces the doctor he believes in certain things about himself which the doctor doesn't believe. The patient has faith in his malady which the doctor doesn't share. Faith is belief. It is a belief in which the thalamus has a stronger share than the cortex. The doctor's reasonable hope for cure rests on making such environmental changes as will alter the emotional status of his patient. The environmental factor of most moment is likely to be the physician himself. He will prevail if his faith is stronger than the patient's faith. Icy reasoning will not suffice. A strong enough faith, even in his placebos, may be enough, but as knowledge advances faith

in placebos declines The faith needs a firm foundation How shall such a foundation be laid?

A great deal is said about changes to be made in the patient's outlook and viewpoint Not much about what the emotional attitude of the doctor shall be Faith is an emotional attitude of warm confidence toward a situation Freud, in discussing the "personal relationship of patient to doctor" asserts that for success in the relationship the patient must love the doctor, the so-called transference This contribution to scientific exposition of the doctor-patient relationship is nothing to startle us He doesn't say that the doctor must love the patient Yet the doctor's attitude toward the patient is perhaps more fundamental than the patient's attitude toward the doctor John Dewey, in his book, "A Common Faith," has shown that the faith to which all wise men, of whatever race or creed, may subscribe is a humanistic faith, and may be expressed as a sublimation and reinforcement of those human relationships that are cherished by every man He must be a father filled with wise benevolence, a brother with consciousness that he shares in embryo all the weaknesses and frailties of the patient, a friend that knows the art of showing himself friendly

Every man knows that emotional attitudes are more readily communicated than ideas A dog or a child can understand an emotional attitude The simplest souls can grasp the thalamic component of belief The subtlest mind also yields to the persuasive drive of emotion, to the affective situation in which he finds himself The dweller in the Orient unconsciously acquires enough of the spirit of acquiescence and inner calm to gain the low arterial tension of Oriental neighbors The faith that heals, heals not through argument but by contagion But to heal, faith must have substance A speculative balance of probability is not enough The faith that heals must have deep roots in the personality of the healer A recent best seller in the realm of popular psychology, "The Return to Religion," written by a well-known psychologist, suggests as a cure for the feebleness of the doctor in the doctor-patient relationship that he return to the rites and formulas of the church It is true that these express in fit and beautiful words many truths that seem to fade and perish when put into the clumsy terms of science

But this suggestion won't help us The faith about which reservations are kept has no living force The faith that will avail the doctor must be grounded in his own psychobiologic conceptions One of the most hopeful moves in medical education is teaching to first-year students the elements of psychobiology A system of belief is implanted best in the young It would be my suggestion that psychobiology be taught in the premedical years, that the doctor-patient relationship be the beginning of medical study A deep insight into this fundamental philosophy is a chief concern of the internist

I know no short definition of the word "internist," but I conceive of him that he is a type of general practitioner who, having delegated to workers in special fields a large number of his cares, has a special opportunity to gain

a vantage-point from which he can get a larger survey of the field of medicine. From this vantage-point he can see what problems press most instantly for solution. He it is who most correctly can select the point where therapeutic emphasis should fall, can judicially assay the worth of the rival claimants for priority in dealing with the sick man's problem.

To him then we would best address the question, "How can the 'personal relationship between doctor and patient' be made more fruitful for good? How can the doctor himself, as a therapeutic agent, be refined and polished to make of him a more potent agent?"

"What shall be the foundation of his faith? Is he to employ the placebos that he scorns when employed by the uncultured, or is he to find a way to educate his public to demand something different, something far better of him?" I leave this discussion in the form of a question, but a very pertinent and pressing question. A right answer will lead to the physician's occupying a position of even greater dignity in the social order than the high place he now holds.

ABSCESS OF MEDIASTINUM FOLLOWING ACUTE TONSILLITIS^{*}

By CHESTER S. KEEFER, M.D., F.A.C.P., Boston, Massachusetts

AN abscess of the mediastinum is a rare complication of hemolytic streptococcal infection of the throat. Recently such a case was observed and, following surgical treatment, the patient recovered completely. A summary of the case follows.

CASE REPORT

Following an acute tonsillitis and pharyngitis, a man develops painful and difficult swallowing, pain between the shoulder blades, fever, and leukocytosis. Examination showed signs of a mass in the posterior mediastinum. Abscess containing hemolytic streptococci drained. Recovery.

A man, 46 years of age, was admitted to the Boston City Hospital on account of fever and sore throat. Five weeks previously he had an attack of coryza and tonsillitis but it was not severe enough to confine him to bed. He continued with his daily work for two weeks, when he was forced to remain at home on account of chills, fever, and difficult and painful swallowing. This was accompanied by attacks of coughing which were productive of mucopurulent sputum. During the third week of his illness the chills and fever continued and the pain and difficulty in swallowing increased. In addition, he had some pain and discomfort about the base of the neck which radiated into the occiput during swallowing. The temperature gradually became lower and he felt somewhat improved insofar as his sore throat was concerned, but the dysphagia continued.

The physical examination showed a man who was acutely ill and pale. He had very few complaints but it was difficult for him to swallow liquids or solid foods. The temperature was 101.5° F. The throat was red and the pharynx seemed edematous and swollen. Palpation of the pharynx failed to reveal any localized mass although the mucous membrane was swollen. The lymph nodes of the neck were not enlarged, and the thyroid was not palpable. The trachea was in the midline and it could be moved lateralward without discomfort, it moved up and down on swallowing but this caused some discomfort. There was no swelling of the neck and no areas of tenderness on deep pressure. The movements of the cervical spine did not seem limited in extent. The examination of the chest failed to show any abnormal areas of prominence and the superficial veins of the chest wall and the jugular veins were not swollen. There was no retromanubrial dullness, no displacement of the heart or mediastinum laterally. The lungs were clear throughout. The heart was in normal position and the sounds were clear. Over the upper dorsal spine there was dullness extending from the first to the fourth dorsal spine, and over this area the whispered voice and breath sounds were distinct and bronchial in character, but aside from these abnormalities there was nothing distinctly abnormal to be made out on physical examination of the chest.

^{*} Received for publication July 27, 1937.

FIG 1 Roentgen-rays of chest in patient with abscess of mediastinum (1) Roentgen-ray on first day of admission (2) Roentgen-ray on fourth day of hospital visit—note the enlarging mediastinal shadow (3) Roentgen-ray of chest 4 days after operation (4) Roentgen-ray of chest 2 months after operation

The abdomen was soft and no organs were palpable. The extremities, genitalia, and reflexes were normal.

Laboratory examinations showed 3,860,000 red blood cells per cubic millimeter and hemoglobin of 74 per cent (Sahli). The total white blood cell count was 25,000 per cubic millimeter with 85 per cent polymorphonuclear cells. The urine was clear and normal.

The roentgen-ray examination showed the heart in normal position, the lung fields clear. In the superior mediastinum there was a bilateral rounded shadow with concave borders, slightly more prominent on the right side than the left. It was distinctly supra-aortic, and it had not displaced the trachea laterally nor the aortic arch downward (figure 1).

Fluoroscopic examination showed that this shadow was retro-esophageal and in the posterior mediastinum. The esophagus was displaced anteriorly and slightly to the left. As the barium entered the esophagus, it paused momentarily at this area before passing downward.

In summary, then, a man had an acute tonsillitis and pharyngitis which was followed by difficult and painful swallowing, fever, and leukocytosis. Examination of the chest showed decreased resonance and increased whispered voice sounds over the upper dorsal spine, a bilateral rounded shadow in the superior mediastinum by roentgen-ray, and anterior displacement of the esophagus by fluoroscopy. From the clinical course of the illness, together with the above findings it seemed highly likely that the process was an abscess in the posterior mediastinum. This clinical diagnosis was supported by surgical operation.

Course of Illness. The course of the temperature is shown in figure 3. On the seventh day of his hospital admission Dr. I. J. Walker operated by entering the posterior mediastinum, resecting a portion of the second, third, and fourth ribs close to their articulation with the spine, and opened an abscess containing 300 c.c. of thin purulent material. The pleura was not entered and a drain was inserted. Following the operation there was an increase in the temperature for several days, but it gradually subsided and returned to a normal level within 14 days. The pus from the abscess contained a pure culture of hemolytic streptococci and the drainage was profuse for several weeks. Due to the anemia, he received two blood transfusions and improved considerably. After several months the cavity gradually diminished so that very little drainage was evident. He gained weight and felt greatly improved. When he was seen two months after the operation, he appeared well, had returned to work, and there was only a small draining sinus in the back.

COMMENT

The subject of abscess of the mediastinum has been discussed most thoroughly in the classical monograph of Hare¹ on mediastinal diseases. More recent essays on the subject are those of Neuhof,² Fischer,³ Lerche,⁴ Lambert and Berry,⁶ Heuer,⁷ Graham, Singer and Ballou,⁸ Farnum,⁹ and Malnekoff.¹⁰

In the present case, it seems likely that the infection of the posterior mediastinum resulted from an extension of the infective process in the pharynx to the retrovisceral space. The anatomical relations are illustrated in figure 2, which is reproduced from Lerche's⁴ paper. It is seen that the retrovisceral space extends directly from the pharynx at the base of the skull to the posterior mediastinum. The other possibility, of course, is that the abscess arose from suppurating lymph nodes in the posterior mediastinum.

White blood cell count is recorded in thousands

This type of infection has been studied extensively by Leiche⁵ who emphasizes the importance of mediastinal lymph node infections in the causation of mediastinitis. It is analogous to the retropharyngeal lymph node infections with abscess formation in children, the main difference being in the location of the infection.

In general, acute mediastinitis is uncommon but, inasmuch as a small number of these cases are of such a nature that they can be treated surgically, it is of importance that they be recognized. For purposes of discussion, it is convenient to divide these cases into two main groups: (1) the diffuse phlegmonous variety and (2) localized abscesses of the mediastinum. Inasmuch as the diffuse phlegmonous variety may be only a part of a more widespread infection and therefore not amenable to treatment it can be dismissed from the present discussion.

Localized abscesses in the mediastinum can be divided, according to the situation of the suppurative process, into abscesses in the anterior or posterior mediastinum. This division is of considerable significance insofar as treatment is concerned.

Abscess of the Anterior Mediastinum An abscess in the anterior mediastinum results from (1) an extension of an infection from the neck, such as erysipelas, or infection following surgical operations, (2) an osteomyelitis of the sternum, (3) suppuration of lymph nodes, (4) an extension of an infection from the lung to the mediastinum. An abscess in this location tends to extend to the exterior and may present in the suprasternal notch or at the anterior border of the sternomastoid muscle. It may gravitate downward and cause a painful, tender area in the region of the xiphoid. Rarely such abscesses may point beneath the sternoclavicular region or perforate into the interspaces in the parasternal line.

Abscess of the Posterior Mediastinum An abscess in the posterior mediastinum results from an extension of an infection from the retropharyngeal space or from the esophagus. Other causes are extension of an infection from the spine, abdomen, lung, or pleural cavity. These abscesses show only a slight tendency to approach the surface and they commonly extend upwards or downwards in the mediastinum. They may rupture into the pleural cavity, the trachea, bronchi, esophagus, or pericardium. Indeed, when they are unrecognized or neglected they may even point in the posterior triangle of the neck or extend to the retroperitoneal space and appear in the groin.

Symptoms and Signs Referable to the Chest or Extension of the Infection to a Neighboring Organ In the main, symptoms arising from pressure of various anatomical structures of the mediastinum are less conspicuous with an abscess than with a neoplasm, and at the onset the symptoms of infection predominate, it is only later that the symptoms and signs of compression occur.

Pain beneath the sternum and radiating into the back, or pain between

the shoulder blades or referred along the intercostal nerves on one side are common features

The irritative phenomena consist of cough, dyspnea, painful and/or difficult swallowing, and painful movement of the trachea, or paroxysmal hypertension. Dysphagia is present when the process is situated in the posterior mediastinum and wheezing respiration occurs when there is compression of the trachea or bronchi, on rare occasions the bronchi may be compressed to such an extent that atelectasis occurs.

On occasions, the development of a mediastinal abscess is so insidious that it may be obscured by the symptoms and signs resulting from the extension of the process to a neighboring organ. The various paths of extension of an infection from the neck or mediastinum have been studied extensively by Lambert and Berly,⁶ Fuirstenberg and Yglesias¹¹ and Collier and Yglesias.¹² It is well to be familiar with the various possibilities, since foci of infection may appear in various areas and have their origin in the mediastinum. Thus, one may find extrapleural abscesses, empyema, abscesses in the neck, or perforation of the trachea, bronchus, esophagus, or lung. More rarely the infection extends to the pericardium, the peritoneum or the retroperitoneum. Infections in these areas, then, should call one's attention to the mediastinum as a possible focus of infection.

Roentgen-Ray Examination of the Chest The roentgen-ray of the chest will show unilateral or bilateral triangular shadows with the apex pointing caudad and superimposed on the heart shadow, or there are rounded or triangular shadows in the superior mediastinum. There may be an associated empyema or extra-pleural abscess which obscures the lung fields. In the case of abscesses in the posterior mediastinum, the esophagus is often displaced anteriorly and to either side of the midline. All of these signs should be looked for and, when they are present, the diagnosis of mediastinal abscess should be entertained. The examination of the patient under the fluoroscope should include both an anterior-posterior view as well as a lateral one. The roentgen-ray diagnosis has been discussed recently by Kornblum and Osborn.¹³

Diagnosis of Mediastinal Abscess The diagnosis of an abscess of the mediastinum depends upon the following features:

- 1 A history or the presence of a condition which is capable of causing a mediastinal infection
- 2 The constitutional symptoms and signs of an infection
- 3 The localizing symptoms and physical signs in the mediastinum due to involvement of various anatomical structures
- 4 Signs resulting from an extension of the process to neighboring organs
- 5 Characteristic roentgen-ray findings in the chest
- 6 Finding an abscess on exploration

When the above features are present one is justified in making a diagnosis of acute mediastinal abscess.

Treatment The diagnosis should be made as early as possible, inasmuch as the only possibility of recovery is surgical drainage of the abscess. There are, of course, the exceptions in which the abscess is drained by rupture into a bronchus⁹ or the esophagus, or by aspiration¹⁰. These instances occasionally occur when the abscess is overlooked and, while recovery may follow such a rupture, it is more common for death to follow such an accident.

In the present case, the posterior approach was used with success. Other methods which are recommended are drainage of the abscess through an incision in the neck with a drainage tube inserted into the mediastinum from this point.

SUMMARY AND CONCLUSIONS

A case of abscess of the posterior mediastinum following tonsillitis due to hemolytic streptococcus infection is recorded. Complete recovery followed surgical drainage of the posterior mediastinum. The clinical features and the course of these abscesses are summarized.

CORONARY ARTERY DISEASE, A HISTORICAL SKETCH¹

By FRANK T FULTON, *Providence, Rhode Island*

INTEREST in any subject is usually accentuated by some study of its early history, and in connection with some of the now well understood diseases a fascinating story may be written

Medical students of 20 years ago seldom, if ever, heard of the clinical diagnosis of coronary thrombosis Angina pectoris on the other hand was frequently discussed, that diagnosis, when made, carried with it in the minds of most, the sentence of a short life, terminating in sudden death Now-a-days coronary thrombosis is up for daily discussion in a routine hospital visit, a fairly good guess can be made as to what artery is out of function and to the surprise of many, more than half of the patients go on to a satisfactory recovery

This short sketch will make no attempt to cover clinical or pathological detail but will deal with incidents and men and their places in the development of our knowledge of coronary artery disease The story, in this instance, as everyone knows, really began with William Heberden, whose first observations were made public in 1768 These were reported at a meeting of the Royal College of Physicians in London Even at the risk of tedious repetition, some of his description will be quoted He had just been referring to the various types of chest pain, vague, inconsequential and otherwise Then he said

But there is a disorder of the breast marked with strong and peculiar symptoms and not extremely rare, which deserves to be mentioned more at length The seat of it, and sense of strangling, and anxiety with which it is attended, may make it not improperly be called angina pectoris

They who are afflicted with it, are seized while they are walking (more especially if it be up hill, and soon after eating), with a painful and most disagreeable sensation in the breast, which seems as if it would extinguish life, if it were to increase or continue, but the moment they stand still, all this uneasiness vanishes

In all other respects, the patients are, at the beginning of this disorder, perfectly well, and in particular have no shortness of breath, from which it is totally different The pain is sometimes situated in the upper part, sometimes in the middle sometimes at the bottom of the *os sterni*, and often more inclined to the left than to the right side It likewise very frequently extends from the breast to the middle of the left arm The pulse is, at least sometimes, not disturbed by this pain, as I have had opportunities of observing by feeling the pulse during the paroxysm Males are most liable to that disease, especially such as have passed their fiftieth year

After it has continued a year or more, it will not cease so instantaneously upon standing still, and it will come on not only when the persons are walking but when

* Received for publication August 14, 1937

they are lying down, especially if they lie on their left side, and oblige them to rise up out of their beds. In some inveterate cases it has been brought on by the motion of a horse, or a carriage, and even by swallowing, coughing, going to stool or speaking, or any disturbance of mind. In one or two persons, the pain has lasted some hours, or even days, but this has happened when the complaint has been of long standing, and thoroughly rooted in the constitution. Once only the very first attack continued the whole night.

I have seen nearly a hundred people under this disorder, of which number there have been three women, and one boy 12 years old. All the rest were men near, or past the fiftieth year of their age.

The termination of the angina pectoris is remarkable. For if no accident intervene, but the disease go on to its height, the patients all suddenly fall down, and perish almost immediately.

One hundred and forty-three years later, before the same society, Sir William Osler, in his second Lumleian lecture said "Had Heberden listened to my first lecture he could have remarked very justly 'Well! they have not got much ahead since my day'." In descriptive symptomatology we have not, and among 100 cases of angina pectoris there is no reason why Heberden should not have met all the important anomalies and complications. He had the good sense not to say much about the cause of the disease, and the good fortune to get very close to the truth in what he did say."

Contemporary with Heberden, were John Hunter, Edward Jenner and John Fothergill. These four were all in more or less intimate association with each other. It is of interest to note the possibility of discussion and conference between these men who, during the life of Heberden, cleared up this subject in such a way that little was added to it for another hundred years.

Hunter, himself, as everyone knows, was a victim of the disease. He was the greatest of the group, being ranked by Garrison along with Pare and Lister as one of the three greatest surgeons of all times. He was 45 years of age at the time of his first attack of angina, with which he was to be tormented for 20 years. Knowing his ailment he said, "My life is in the hands of any rascal who chooses to annoy and tease me." In a fit of anger at a meeting of the governors at St. George's Hospital, he had an attack, left the room and fell dead.

Heberden, a typical practitioner of that time, was 58 years old at the time of his first publication. He was a Cambridge graduate and an outstanding Greek and Hebrew scholar. His commentaries were written in Latin and were published in 1802, a year after his death. Of this it has been said—"The little book is one of the shining monuments of medical scholarship." Heberden died at the age of 91.

Fothergill, but two years younger than Heberden, was a Quaker, a successful and wealthy London practitioner, a friend of William Hunter. He was also a friend of Franklin and of the American colonies and in some measure aided in the founding of the Pennsylvania Hospital. He, in 1776, reported a fatal case which came to autopsy. The autopsy was performed

by Hunter whose description was rather meagre, the findings being in the main, negative, except as expressed in the last sentence as follows "The two coronary arteries from their origin to many of their ramifications upon the heart were become one piece of bone"

Jenner, the youngest of the four, was a favorite pupil of Hunter's and a close friend for many years. He was in practice at Berkeley in Gloucestershire and at this time was 27 years of age. Hunter, in the year 1776, the same in which he did the autopsy for Fothergill, had his second attack of angina. While he was convalescing at Bath he consulted Jenner about his ailment, who, in turn wrote to Heberden giving his diagnosis. The letter in part was as follows

"When you are acquainted with my motives I presume you will pardon the liberty I take in addressing you. I am prompted to it from a knowledge of the mutual regard that subsists between you and my worthy friend, Mr Hunter. When I had the pleasure of seeing him at Bath last autumn I thought he was affected with many symptoms of the angina pectoris. Though in the course of my practice I have seen many fall victims to this dreadful disease, yet I have only had two opportunities of an examination after death." He then describes the condition of the coronary arteries which he had noted at autopsy, adding, "As the heart, I believe, in every subject that has died of the angina pectoris, has been found extremely loaded with fat, and as these vessels lie quite concealed in that substance, is it possible this appearance may have been overlooked? The importance of the coronaries, and how much the heart must suffer from their not being able duly to perform their functions (we cannot be surprised at the painful spasms), is a subject I need not enlarge upon, therefore shall just remark that it is possible that all the symptoms may arise from this one circumstance

"As I frequently write to Mr Hunter I have been some time in hesitation respecting the propriety of communicating the matter to him, and should be exceedingly thankful to you, sir, for your advice upon the subject. Should it be admitted that this is the cause of the disease, I fear the medical world may seek in vain for a remedy, and I am fearful (if Mr Hunter should admit this to be the cause of the disease) that it may deprive him of the hopes of a recovery"

Referring to these autopsies at a later time, Jenner wrote to Parry

At this very time, my valued friend Mr John Hunter, began to have the symptoms of angina pectoris, too strongly marked upon him and this circumstance prevented any publication of my ideas upon the subject as it must have brought on an unpleasant conference between Mr Hunter and me

From the studies and observations, then, of these men originated the correlation of the symptoms of this condition, the introduction of the term "angina pectoris" and the idea that these symptoms had a very definite relationship to coronary sclerosis

Caleb Hillier Parry was in close association with this group for although he was six years younger than Jenner, they were boyhood and lifelong friends. He at one time spoke of Jenner as a friend of forty years, "acquired in the gay morning of my life". Parry was a famous practitioner of Bath, chiefly known by his account of exophthalmic goiter which antedated both Graves and Basedow. To him Jenner dedicated his work on

Vaccinia Parry's article on angina pectoris was written when he was 44 and two years before the death of Heberden. This monograph appearing in 1799 was without doubt the best discussion of the subject at that time and, in fact, for many years later. On the title page of the monograph appears the following "Inquiry into the Nature and Causes of the Angina Pectoris as they are Deducible from the Actual Symptoms and from Dissection." He then writes in his introduction "Such an inquiry will unavoidably involve me in the necessity of pointing out what appear to me the mistakes of some of my medical brethren in their nosological judgment of this disease. In a personal view this is a disagreeable task but when I consider that truth is the sole foundation of moral and religious virtue and therefore of happiness, my regard to personal delicacy is lost in a more general and greater obligation of public utility. In reality it is of little importance who is the discoverer of truths, however valuable. To mankind it suffices that the truth is actually known and the good obtained." One might add here that Parry gives Jenner full credit for the suggestion that angina pectoris arose from some heart changes, probably ossification or some similar disease of the coronary arteries.

There was a very important observation by Allan Burns published in 1809. This suggested the idea upon which the theory of intermittent claudication is based and the theory which is now quite generally held, namely, that the pain of angina pectoris is due to a relative ischemia. In his observations on "Diseases of the Coronary Arteries and on Syncope Anginosa" he speaks of the effect upon the leg of the application of a tourniquet, which would prevent satisfactory circulation, namely, the early fatigue of the muscle below the ligature. He likens that to the inelastic and incompetent coronary arteries and suggests it as a cause of the pain of angina.

After this publication of Burns there appeared to be no outstanding observations or publications about the coronary arteries until the time of Latham, 1845. This is the more remarkable because that was the period of the distinguished group of Irish clinicians, among whom were Adams, Cheyne, Colles, Corrigan, Graves and Stokes.

Latham was at one time physician to St. Bartholomew's, but gave up the position on account of his health. Later he published a book—"Diseases of the Heart"—based on his hospital lectures. Stokes said of this "The two concluding lectures of Dr. Latham should be carefully studied, not only as bearing on the disease in question, but as fine examples of medical writing." These last two lectures of Latham just missed being epoch making. Much that he wrote cannot be paraphrased without a definite loss of picturesqueness and charm of expression and in consequence will be quoted.

Angina pectoris from the time it was first described by Dr. Heberden has always had a large share of attention paid to it. Much has been written about it, and well written, by some of the best men in our profession. But it is still of very doubtful

pathology, and its pathology has little chance of being further illustrated, unless there be a clear agreement among us what we are to understand by the thing itself

I believe that the definition, which has been given, includes all that is proper to angina pectoris and excludes all that is not, and that it consists essentially of pain in the chest and a sense of approaching dissolution. Not from the absolute constancy but from the very great frequency of its occurrence there is one more element, which has a claim to be considered almost as a part of the disease. Its very peculiarity forces it upon our notice. It is an extension of the pain to one or both arms, most frequently to the left and stopping at the elbow, sometimes to the right, and sometimes to both, and sometimes reaching to the fingers.

But what is angina pectoris? Its symptoms, striking and definite as they are, do not carry their own interpretation along with them. They tell neither whence they are nor what is their efficient cause. (To that end) we must gain what help we can from the many circumstances which various clinical histories and various dissections have disclosed and there are plenty of such histories and dissections upon record. I have both seen many and read many. But all the cases which one sees or reads of a particular disease do not necessarily add to our knowledge. They may make the knowledge which we have, more familiar without augmenting it. They may freshen our experience without enlarging it. Yet some one case out of many from peculiar circumstances belonging to it may teach us something, which we did not and could not learn from all the rest.

Thus, I have three cases of angina pectoris to report, two falling under my own observation and a third coming to me upon the best authority, which added something at least to my knowledge of the disease.

He then reports three cases in detail. All came to autopsy. One of these was Thomas Arnold of Rugby, who with his father, William Arnold, and his son, Mathew Arnold are frequently referred to as illustrating the familial tendency of the disease. After the detailed accounts of these cases he writes

Here then are three cases of angina pectoris. In the first we have death in a fortnight, in the second death in ten days, in the third death in less than three hours, from the first seizure. Now circumstances cannot be conceived more favourable than those which these three cases present for ascertaining the connection between symptoms declared in the living, and changes of structure found in the dead. The symptoms were essentially the same in all. They were few and striking and constituted of actions and sufferings which manifestly could, and manifestly did, cause death. They were also uncomplicated, no other symptoms interfering to spoil the simplicity of each case, before death arrived.

There are no cases upon record in which death followed the first accessions of angina pectoris so rapidly, as in those three which I have related. And if the disease essentially proceeds from any material element which morbid anatomy can detect, these were the cases in which to find it. You know what *was* found in these cases. Unfortunately for the success of our inquiry, not the same thing in all. Extreme muscular attenuation in two, and muscular attenuation of less degree conjoined with ossified coronary arteries and an ossified aorta in the third. But had there been simple ossification of the coronary arteries in all or simple muscular attenuation in all, yet could neither one nor the other be regarded as the proper efficient cause of angina pectoris. For though one or both are often traceable among the complex forms of disease found in those who die at later periods, yet one and both are often entirely absent. What then have these cases, so new and interesting in their details, taught us after all? They have taught us that angina pectoris has a greater, an earlier, and more instantaneous power to kill than it was ever hitherto thought to have, and they

have (in this way) enlarged our knowledge of its clinical history, and have thus enabled us perhaps better to understand its real nature

One cannot escape the conviction that these three unusually rapidly fatal cases so well described and discussed by Latham were what is now so easily and often recognized as coronary thrombosis. His differentiation from the angina of effort of Heberden was complete. He even went so far as to put them in a class by themselves and only failed in that he failed to discover the fundamental condition which made them different. Knowing the ease with which thrombosis in a coronary artery may be overlooked, this failure is easy to understand.

In Stokes' book on "Diseases of the Heart and Aorta" in 1854, a book of 600 pages, he allows 8 pages for the discussion of angina pectoris. Most of that discussion refers to the ideas of Heberden, Parry and Latham. He writes

Upon the whole, we may conclude, that the special group of symptoms described as angina pectoris by Heberden, Parry, Percival and Latham, is but the occurrence, in a defined manner, of some of the symptoms connected with a weakened heart. *Obstruction of the coronaries may or may not be present, and is probably not infrequent, but as the cause of angina, its action is remote, and its existence unnecessary.**

Majoi, in his "Classic Description of Disease," gives the credit to Adam Hammer for having first made the diagnosis during life of coronary thrombotic occlusion. Hammer was a German who apparently for political reasons left Germany after the revolution of 1848 and came to this country and, with some associates, established a medical school here. Briefly, the case which Hammer reports and which was reported in *Wiener Medizinische Wochenschrift*, 1878, was as follows. He was called by one of his younger colleagues to see a patient who was apparently in extremis, and after consideration of the history, the symptoms and signs, he told his colleague at the bedside, that these symptoms could only be produced by thrombotic occlusion of at least one of the coronary arteries. The colleague replied, "I have never heard of such a diagnosis in my whole life" and Hammer writes "I answered, 'Nor I also'". Subsequent autopsy showed that the right sinus of Valsalva contained a thrombus which had ultimately completely shut off the lumen of the artery.

This, however, is not at all the type of occlusion which is now so commonly seen in which the thrombus is formed somewhere within the course of the artery, and which is usually due to arterial disease. To George Dock in 1896 has long since been given the credit for having observed and discussed a case of this type and having ventured the diagnosis while the patient was living. He saw the patient about a week after the onset of cardiac pain. His description of the onset and the history at that time was about what one notes now in an ordinarily severe case. The sounds were faint but clear. There was a loud double friction sound at the apex region. There were loud moist râles in the lungs. After giving an

* Italics not in the original

account of the symptoms and signs, he writes "The diagnosis was myomalacia following coronary sclerosis with secondary pericarditis. This was based on the history of increasing dyspnea and heart pain without evidence of disease in the lungs or kidneys, or other (valvular) disease of the heart, the history of the acute attack indicating infarction, and the acute onset of pericarditis without other cause." The same day against orders the patient got out of bed to go to the toilet and suddenly died. The autopsy showed a thrombosis of the descending branch of the left coronary and a resulting infarct.

Osler's "Angina Pectoris and Allied States," a volume of lectures delivered in 1896, is rich in references to the symptoms and pathological findings of coronary artery disease, and it is not easy to understand why the correlation of these signs, symptoms and findings was not made earlier. For example, in discussing the coronary arteries and speaking of the descending branch of the left coronary artery, he says

"This anterior branch is the important one in the morbid anatomy of the coronary arteries, since it is by far the most frequently found seat of extensive sclerosis or of embolism or thrombosis. It may be called the *artery of sudden death*." He writes further on—"The effect of plugging of the artery is the production of what is known as an anaemic infarct, a well-recognized pathological condition, the consideration of which need not detain us. A very important matter relates to the effect of plugging of the coronary arteries upon the heart-beat, the contractions become of the type known as fibrillary, and it is difficult or impossible to get the organ to resume the ordinary coordinated beats, though experimentally this has been done, even after fibrillary contraction has been established."

In demonstrating a pathological specimen, he said "In this anterior coronary artery you see a firmly adherent thrombus, which completely occludes the descending branch, to the lumen of which it is firmly attached. It was taken from a man about fifty years of age, who had mitral-valve disease and had a good deal of cardiac dyspnoea. Early one morning he was seized with a severe pain about the heart and shortness of breath, and died in a very few moments. No doubt the sudden death was due to the blocking of the anterior branch of the left coronary artery by the thrombus."

"When the occlusion has persisted for any length of time before death the condition of anaemic necrosis may be found. The man with a fresh thrombus in the anterior branch of the left coronary artery probably died in a paroxysm of angina, but he had not had previous typical attacks. As I will tell you later on, the affection is rare in hospital practice so that we do not have opportunities of making the inspection of the bodies of persons who have died of the disease." With reference to its rarity in hospital practice he elsewhere said "During the ten years in which I lived in Montreal, I did not see a case of the disease either in private practice or at the Montreal General Hospital. At Blockley (Philadelphia Hospital) too, it was an exceedingly rare affection. I do not remember to have had a case under my personal care. There were two cases in my service at the University Hospital. During the seven years in which the Johns Hopkins Hospital has been opened, with an unusually large 'material' in diseases of the heart and arteries, and with many cases of heart pain of various sorts, there have been only four instances of angina pectoris. You will find the statement in Fagge's Practice (third edition, vol. II, p. 26) that 'the writer has never seen classical angina in hospital practice.'"

In a large consultant practice it was more frequently seen. For instance, Dr. Balfour at that time had analyzed 98 cases which came under his observation in 10 years. Osler said that his own experience had embraced a series of 60 cases, 40 of which he considered to be true angina.

The views and arguments currently put forward as to the reasons for the real or apparent greater frequency of coronary thrombosis at the present time will not be discussed here.

The mechanism of instantaneous death has always been a problem and a problem which has had much discussion and various explanations. Lately we have come to believe that in many cases in which death in coronary artery disease is instantaneous it is due to ventricular fibrillation. So long as 40 years ago when these lectures were written, Osler made a significant suggestion in speaking of Kronecker's coordination center, of which the "knowledge is still very indefinite." He said

"I have seen Kronecker perform the experiment, and certainly when the point in the dog's heart is pricked—it is situated about the lower limit of the upper third of the ventricular septum—the organ becomes paralyzed in a state of fibrillary tremor, from which it does not recover. This point is within the area of distribution of the anterior coronary artery, the vessel oftenest found plugged by thrombus or embolus in cases of sudden death."

In another lecture he says, "It does not fall to the lot of many physicians to witness the sudden death in angina but there are observations to show that the pulse beat and the heart stop abruptly. Dr. Thayer (who was present in one instance) tells me that the death seemed instantaneous—the pulse ceased *at once* and there were no further heart beats. As I have before remarked, the mode of death resembles that produced by Kronecker's heart puncture."

In still another lecture speaking of these cases of sudden death, he said, "An explanation of the awful suddenness is probably to be found in the arrest of the heart in fibrillary contractions such as take place experimentally in animals after ligation of a coronary vessel."

Osler describes two cases under the heading of "Rapidly Repeated Attacks of Angina over a Period of Days or Weeks, with the Development of a State of Cardiac Asystole." These he apparently considered belonging in the class of status anginosus. One lived six days, the other 19. The perusal of the history leaves no doubt in the mind of the reader that these two cases were instances of coronary thrombosis. He remarked that he had seen but two cases of this type.

In discussing Allan Burns' Theory, he said

"Very different to this relative ischaemia of the cardiac muscle must be the condition following the blocking of a large branch by a thrombus or an embolus*. The resulting anaemic infarct, if at all extensive, must cause not alone great weakness of the cardiac muscle, but at the site of the lesion the smooth uniformity of the waves of contraction must be seriously interrupted. This cardiomalacia may lead to rupture of the wall of the ventricle (eleven cases in Huchard's collection of autopsies) or *may cause pericarditis*†. While the anaemic infarct is a well-recognized lesion in fatal

* In this sentence Osler differentiates between angina pectoris and coronary thrombosis.

† Italics not in the original.

cases of angina pectoris, it must be remembered that a paroxysm of pain is really a rare complication of this not infrequent change. It is interesting to note that the scars of infarcts have been found years after recovery from attacks of angina."

Again we have an illustration of how long a time it sometimes takes for a well established medical fact to be recognized and accepted. It is no doubt true that in Latham's time, postmortem examinations were not nearly so carefully made. Pathological processes were not so easily recognized or so well understood but we know that at the time of Osler's writings, these processes were well understood and that autopsies were carefully made and that Osler was an extraordinarily well trained pathologist and clinician. While Osler put these cases of coronary thrombosis in a group by themselves, his experience with them at that time was so limited that it apparently seemed to him as it did to many others for a number of years that thrombus formation in a coronary artery with a resulting infarct was simply an incident in the course of coronary disease which, as a rule, immediately preceded death and was not of particular importance clinically. This in the face of the fact that he makes the definite statement that healed infarcts were frequently found post mortem.

It was another 16 years before Herrick's observations were published indicating that thrombosis may occur and recovery take place with subsequent years of satisfactory life. So far as the clinical diagnosis of sudden thrombotic obstruction of the coronary was concerned, it remained for Herrick to bring order out of the confusion. In his paper of 1912 he described most of the symptoms which we now recognize as being associated with thrombosis: persistent pain, ashy pallor, sweating, nausea, vomiting, abdominal symptoms which might be confused with abdominal surgical conditions, râles in the lungs, arrhythmia, feeble pulse, dyspnea, cyanosis, pericarditis, fever, as well as some changes in the electrocardiogram. This paper was read before the Association of American Physicians, published in the *Transactions* and also in the *Journal of the American Medical Association*. However, scant notice was taken of the subject even then until after his second paper, six years later, in which he reported more cases and emphasized again what he had before published. His observations and suggestions did much to take the condition out of that group of fatal diseases in which the diagnosis is only of academic interest, for he emphasized particularly the opinion that many cases of thrombosis were mild and that recovery frequently did take place. From that time interest in the subject became gradually more widespread until familiarity with the disease became quite universal.

After all, the more familiar one becomes with angina pectoris and coronary thrombosis, the more one realizes that—if we are right in the prevailing theory of what angina pectoris is, namely that it is due to the relative ischemia of the heart muscle—these two conditions would seem to be but different manifestations of the same thing, having as their common basis

coronary artery disease In one the obstruction develops slowly, is progressive, but is partial, while in the other it is sudden and complete The latter condition is a very common termination of the former The important reason for their differentiation is that the two conditions require very different treatment Probably in no other malady does the failure to make a correct diagnosis so frequently contribute to a fatal outcome, as in coronary thrombosis

EFFECTS OF TREATMENT ON RADIUM AND CALCIUM METABOLISM IN THE HUMAN BODY *

By JOSEPH C AUB, ROBLEY D EVANS, DARIUS M GALLAGHER, and
DOROTHY M TIBBETTS, *Boston, Massachusetts*

IN 1924 Blum, a dentist,¹ and in 1925, Hoffman¹ suggested that radium produced necrosis of the jaw. Our knowledge of the pernicious effects of stored radium salts in human beings dates essentially from the publications in 1925 of Castle, Drinker and Drinker² and also Martland³ when necrosis of the jaw in workers who had absorbed radium salts was reported and discussed. Since that time, increasing numbers of similar cases have been recorded. Other abnormal clinical results of radium have been the appearance of severe anemias as well as a high percentage of osteogenic sarcoma, first described and discussed by Martland,³ in 1931.

In the intervening years, several interesting investigations have been reported regarding the storage and excretion of ingested radium salts, and have been summarized by Evans.⁴ Thomas and Bruner⁵ gave radium chloride subcutaneously to eight rats. These animals developed a secondary anemia and the bones subsequently showed a hyperplastic bone marrow in the middle of the shaft while an aplastic marrow was found toward the epiphyses. We found a similar appearance in the bones of one human case (C I). Only 25 per cent of the injected radium was found in their animals after an average of 21 weeks of injections, followed by 57 days of rest. Approximately 50 to 65 per cent of the injected radium was eliminated one week after the first injection, whereas later average elimination of radium, established for two of the animals, was estimated to be 0.6 per cent per week.

Schlundt and Failla⁶ in 1931 studied radium excretion in humans and found that over 90 per cent of radium taken by mouth is eliminated within five days—yet the daily rate of excretion long after exposure was but a small fraction of the total still stored in the bones.

In 1926 a new treatment of lead poisoning was recommended by Aub and Minot,⁷ based on the observation that lead in the body parallels the calcium metabolism, and utilizing the available methods of influencing calcium in the bones to control the circulation of lead. In 1929, Flinn and Seidlin⁸ reported that such "deleading" therapy with parathyroid extract caused an increased excretion of radium. In 1931, Flinn⁹ reported excellent re-

From the Medical Laboratories of the Collis P. Huntington Memorial Hospital of Harvard University and the Physics Department of the Massachusetts Institute of Technology.

This is No. XXIII in the series of papers entitled "Studies of Calcium and Phosphorus Metabolism."

sults with the use of large doses of viosterol. No collection of excreta was made, but electroscopic tests of the patient were made both by gamma ray method and by radio-activity of the expired air, according to the method described by Schlundt, Barker and Flinn.¹⁰

These findings of Flinn's were questioned by Craver and Schlundt,¹¹ who studied four radio-active girls. They were given a low calcium diet and injections of parathyroid extract starting with 10 units every other day and increasing to 50 units a day. They were then given three weeks of high calcium diet with viosterol up to 30 drops a day, followed by three weeks of low calcium diet plus parathyroid extract, and then again given a high calcium diet with viosterol. Only the last three days of each period were analyzed. The results showed an increase of radium excretion in all the analyses with low calcium diet plus parathyroid medication, and equivocal effects from viosterol. They arrived at the conclusion that neither the administration of parathyroid extract nor of viosterol causes a substantial reduction in the total deposited radium.

As with nearly all excellent pioneering work, the technics used in these earlier investigations may be improved. Flinn gave no figures of excretion rate of radium salts. Craver and Schlundt had the patients prepare their own diets and collect their excreta in their homes, but also alternated low and high calcium diets, which reduces the influence of the treatment on stored heavy metals subsequent to the high calcium diet. Neither the parathyroid extract nor the viosterol was adequate greatly to increase calcium excretion, indeed, the viosterol was given probably only as an aid to calcium absorption.

Because of these divergent results, and because of the greatly improved methods available to us, both in metabolic technic and radium analyses, we decided to reinvestigate this problem of radium excretion and of the treatment in cases of stored radium.

Methods The three patients were put on our routine metabolic regime,¹² and were kept in the hospital during their study. The preparation of their diets and their general management was done with the greatest possible accuracy. Collection of their urine and feces was repeatedly checked in our usual routine manner. The patients were most cooperative, and ate their full diet daily, and there were no known errors made in the collection of excreta throughout their stay in the hospital. The urines for three days were measured and mixed, and an aliquot preserved with hydrochloric acid for calcium analysis. The preparation of the remainder of urine for analysis of radium was the entrainment reaction used by Fairhall¹³ for the precipitation of lead, which was found effective for the separation of radium. The precipitate of alkaline phosphates was subjected to wet digestion by nitric acid, dried, and extracted with hydrochloric acid. The entire feces for each period were mixed and digested on the steam bath with nitric acid until a clear solution was obtained. This extract was used for both radium and calcium determinations.

Calcium determinations were made by the method of Fiske and Logan¹⁴ Radium determinations were made by the method of Evans¹⁵ Determinations of total radium in the body, as well as expired air samples and blood samples were also made by his methods¹⁶ The chemicals used disclosed no measurable evidence of radio-activity except the nitric acid which contained not more than 1.5×10^{-12} gram of radium per 100 c c, an amount which would not affect the results of our analyses

The excretion of radium has been shown to be very rapid at first and then eventually to settle down to a very small excretion which is but a small part of the remaining stored radium Schlundt⁶ found that when he drank radium in water he excreted over 90 per cent of the radium in the subsequent five days Seil, Viol and Gordon,¹⁷ and Schlundt, Nerancy and Morris¹⁸ found that the elimination of soluble radium salts was rapid the first week after injection but decreased to less than 1 per cent per day in the next few weeks In two chronic cases, 12 years after exposure, Schlundt and Failla⁶ found an excretion of only 0.002 to 0.005 per cent per day, or about 0.1 per cent per month High initial excretions were also obtained in rats by Thomas and Bruner⁵ These findings are well confirmed in our observations One of our patients (Pt 3—R. L.) had inhaled radium only seven weeks before entering the hospital Though he was harboring only about 4 per cent of the amount that is stored in our more chronic cases yet his rate of radium excretion was approximately six times greater than theirs and had been even higher three weeks previously (table 4) The explanation for this appears to depend largely upon the distribution of radium in the body It has been shown that lead,¹⁹ thorium B,²⁰ polonium,²¹ and radium,⁵ itself, are scattered through the soft tissues as well as in the bones soon after administration In the case reported by Cameron and Viol,²² though they did not analyze bone, radium was still widely distributed in the rest of the organism 3½ months after intravenous injection Gradually, these abnormal metals are excreted or stored preponderantly in the bones Recent work by Calhoun, Hudson and Axel²³ has shown a gradual change in distribution in the bone, itself At first a heavy metal is stored largely in the bone trabeculae, there being from 11 to 16 times as much per gram in the trabeculae as in the cortex of the bone During the following months there is a redistribution and the concentration becomes equal in both trabeculae and cortex Because the cortex is far heavier than the trabeculae, this means that most of the radium is stored in cortical bone This distribution indicates an explanation for the variation in radium excretion The wide distribution in soft tissues and then the accumulation in the bones implies considerable circulation in the blood and therefore a chance for rapid excretion The first large surge in the excretion of these inorganic salts are readily deposited and are easily removed and then a continued though less rapid excretion When the radium finally accumulates in the cortex, it is to be expected that excretion would be relatively poorly influenced by therapy.

The Route of Excretion Seil, Viol and Gordon¹⁷ and Schlundt and Failla⁶ showed that 90 per cent of radium is excreted in the feces. Our experience agrees roughly with this figure. We find the radium in the feces varies with that found in the urine, even during periods of artificially accelerated excretion. Thus in patient 3 (R. L.) the fecal elimination is 96 to 99 per cent of the total excretion in all the periods, in patient 2 (E. C.) it is 94 to 99 per cent in all but two periods (19 and 21), and in patient 1 (M. H.) it varies between 88 to 94 per cent. This is a constant value as judged by usual metabolic variations, indeed far more constant than found for other inorganic salts. Lead is largely excreted in feces and nearly all the increase from therapy appears there.²⁴ Mercury, however, is excreted more in the urine than the feces, though a low calcium diet plus ammonium chloride increases fecal excretion ten fold and urinary excretion only three and one-half times.²⁵ None of these metals are normal constituents of the body except in minimal concentrations in contradistinction to calcium, which is fairly closely related to them chemically. When stored calcium is excreted, on our low calcium diet without medication, about two-thirds of it appears in the feces, but nearly all of the increased excretion induced by therapy (excepting that produced by thyroid) appears in the urine. Therefore, there is no constant relationship between urine and fecal excretion ratios in different heavy metals. What induces fecal excretion and what part of the intestinal tract is involved is not well known. It has been shown that lead can be excreted in considerable amounts in the bile.⁷ Salant and Meyer²⁶ found that radium excreted in feces came particularly from the liver and small intestines. We have had an opportunity to get some further information in regard to radium and biliary excretion. A patient (C. I.) who had $5 (\pm 1) \times 10^{-6}$ gram of radium in her body was found at autopsy to have a good many, though light gall stones. The results of the analyses of one-half (1.83 gm.) of the total sample disclosed that there was 0.032 gram of calcium and 0.022×10^{-9} gram of radium per gram of gall stones (table 3). It is thus clear that radium, like lead, may be excreted through the bile into the intestinal tract. The ratio Ra/Ca is lower in the gall stones than in the bones (see table 3), which may be accounted for by the relatively small concentration of radium and hence only a partial precipitation in bile. Obviously, this does not permit a quantitative interpretation of the concentration or rate of radium excretion.

From these observations, it appears that radium excretion is analogous to that of lead and that (1) approximately 90 per cent of excreted radium appears in the feces, both with normal and stimulated excretion and (2) that some of the excreted radium occurs in the bile, for radium was found in the gall stones of a patient with radium poisoning.

Results of Treatment The problem of the treatment of radium poisoning was studied in three individuals who had received their store predominantly by different routes: (1) intravenous, (2) by mouth, and (3) by inhalation. Two of the patients represented chronic effects with obvious

symptoms, while the third had only recently absorbed a small amount of radium without deleterious effects

CASE REPORTS

Patient 1 (M H) had received an undetermined amount of radium intravenously ten years before entrance to the hospital. This was given as therapy for a minimal amount of chronic arthritis, which had not subsequently progressed. On admission she was suffering from severe necrosis of the jaw of two years' duration. Eight months before entrance she had devoted six weeks in her home to a low calcium diet plus ammonium chloride and thyroid extract. Therefore, this was her second course of treatment, and it is to be expected, from our experience with lead, that the results obtained in the hospital would be of lower magnitude as a result of this previous therapy. At the end of her hospital stay, she had 15.2 (± 1) micrograms of radium stored in her body. This was determined by adding 8.5 micrograms of radium determined as radium C gamma rays plus 6.7 micrograms found as radon in an analysis of expired air (1.7×10^{-10} Curies of radon per liter) (table 5)

| 16 | Diet plus Ca gluconate (10.0 gm Ca) | | | 11.0 | 0.52 | 0.21 | 2.3 |

Without medication she excreted an average of 0.8×10^{-9} gram of radium per day which is about 0.005 per cent of her total body radium. From the laboratory data as disclosed in table 1, it is clear that the use of a low calcium diet plus ammonium chloride, plus thyroid and parathyroid extracts⁷ increased her radium excretion six to eight fold during the period of maximum medication.

The control period, obtained five weeks later, corresponded to the original output of radium. It must be pointed out, however, that the rate of excretion of these chronic cases of radium poisoning is of an extremely low magnitude. In spite of the fact that this medication definitely increased the radium elimination, the total increase remained but a small fraction of the total radium which was stored in her bones, for she only excreted approximately 0.1 microgram more than would have been eliminated without this therapy. This represents an increase of only two-thirds of 1 per cent above her normal rate (0.15 per cent) of elimination per month. Yet there was a striking improvement in the condition of her mandible. Before treatment, the necrosis of bone had progressed during two years to such an extensive bone destruction that her very able dentist had told her not to yawn for fear that she would fracture her jaw. Following this therapy, the sinuses in the bone promptly disappeared and the bone healed into a respectable and quite normal-looking jaw.

FIG 1. Roentgenograms of the same area of mandible of Patient 1 (M. H.). I Taken before treatment, showing necrosis of mandible. II Taken nine months later, and one month after second course of treatment.

The roentgen-ray photographs indicate this striking change (Figure 1). In the two years which have followed this observation, this condition has continued well, except for a single, very small and superficial spicule of bone which remains in the gum. This striking improvement occurred in spite of the fact that only a small percentage of the total radium stored in her body could have been eliminated during the course of this treatment.

Patient 2 (E. C.), a woman of 30 years, was a dial painter from the time she was 16 years of age. From her industrial surroundings it is obvious that most of the radium which she had stored was accumulated in the first seven years of her exposure, and that in the last seven years exposure must have been slight. This is based upon the fact that cleanliness of the

factory was greatly improved, and the technic of applying paint was changed from mouth-pointed brushes to the use of sharp glass pencils. The evidence for early accumulation of radium in this patient is also shown in her bones.

From roentgen-ray pictures it may be seen that obvious damage had been done before the epiphyses at the head of the humerus and the femur had united, with the result that this area of the bones shows distinct lesions.

FIG 2

FIGS 2, 3, and 4. Roentgenograms of Patient 2 (E. C.). These disclose the abnormal epiphyses, and varying degrees of bone destruction and proliferation.

and abnormal union (Figures 2 and 3) It is well known as a result of the observations by Vogt²⁷ and Park,²⁸ and our own analyses²⁰ that the heaviest deposit of lead in the bones of children is at the epiphyses It is

FIG 3

highly likely that radio-active salts have a similar predilection for epiphyseal areas, because in rats they are also the areas most heavily impregnated with thorium in the observations of Behrens and Baumann²⁰ and with radium as judged by the picture published by Thomas and Bruner⁵ (their figure 15)

This is also true of radio-active lead in dogs²³ It, therefore, seems quite clear that the bone lesions in this patient represent deleterious radium effects obtained from a high concentration of radium in the ununited epiphyses. As the upper epiphyses of the humerus normally unite at 20 years of age, and of the femur at 18 years, one must expect that its effect occurred before this age.

FIG 4

Here, then, is a patient who had been exposed to radium for 14 years, with most of the exposure in the first seven years. The deleterious physical effects which she manifested obviously dated back to this early exposure. One cannot say, however, that she was entirely free from exposure during the last seven years. Very careful calibration of the radium in her body disclosed that she had $18 (\pm 1) \times 10^{-6}$ gram of radium stored in her body. Gamma ray measurements indicated that the radium was distributed non-uniformly, in the manner characteristic of radium poisoning.¹⁶

This patient was an excellent subject for metabolic study, for she co-

Bracketed figures represent combined analyses

operated very well in every way. We were, therefore, able to obtain a very complete and accurate metabolic observation. For the first two periods she was on a normal house diet, and at this time her normal rate of radium excretion was determined, and found to average 0.9×10^{-9} gram per day which is approximately 0.005 per cent of the total radium in her body. From then on the course of her metabolic studies is indicated in table 2.

The results of the observation indicate that the various metabolic procedures which we used caused an increase in radium excretion roughly parallel to the calcium excretion. A low calcium diet, plus thyroid extract, and the acid-producing salt, ammonium chloride, definitely raised the radium excretion just as it did in Patient 1, and throughout the various periods of medication the radium excretion remained between three to four times the control values.

The addition of magnesium gluconate to therapy was accompanied by a slightly increased amount of ammonium chloride in order to partially neutralize the alkaline magnesium gluconate. In spite of the reduced acidity of this regime, both radium and calcium excretions were elevated by the magnesium gluconate, and this was the only therapy which seemed to increase the relative proportion of radium excreted in the urine. This finding corroborates the similar finding of Tibbetts and Aub³⁰ of the effect of magnesium ingestion on calcium excretion.

The radium excretion, however, does not always parallel the change in calcium excretion, thus in the periods of no medication (23 to 25), the calcium excretion had returned to a very low level, but the radium excretion continued relatively high. In the last four periods (36-39), in which a high calcium diet was given, in spite of a definite storage of calcium at that time, the radium excretion still remained well above its original level. This may be accounted for by the fact that vitamin D has a metabolic effect which certainly lasts a month. The fact remains, however, that the excretion of radium varied much more sluggishly than that of calcium. This may well be due to the fact that heavy metals, when liberated from bone, are stored in various soft tissue organs such as the liver, lungs, and kidney. When such a storage occurs, one would expect an elevated excretion to continue just as it does in acute cases.

Several other phenomena occurred in this observation which are of importance. This patient did not respond at all to very large doses of parathyroid extract (Lilly), either in the blood calcium level or in the rate of calcium excretion. This can be seen by comparing the calcium excretion in periods 8 to 10 with that in periods 11 to 16. Nor was there any dramatic change in radium excretion during this medication, inasmuch as the radium progressively increased in excretion throughout periods 6 to 16. We are certain that this batch of parathyroid extract was potent, for it was retested on dogs both by Eli Lilly Company and by us, and a satisfactory elevation of blood calcium was obtained. Why then did this patient not respond except by a slight lowering of blood phosphorus level? A possible

explanation is that her osteoclasts were sufficiently damaged so that they were unable to respond to the normal stimulus of parathyroid extract, and were, therefore, unable to liberate bone salts. Further evidence of damage to bone cells is suggested in this patient by the low level of phosphatase in the blood stream (normal is 0.15 Kay units) which would suggest that the osteoblasts were relatively inactive. The phosphatase determinations of this patient (0.06 Kay units) did not vary throughout the observation. In spite of this suggested injury to her bone cells, however, this patient was still able to store calcium at a rapid rate in the first periods of high calcium diet toward the end of her observation.

Another medication to which there was no dramatic response was very large amounts of activated ergosterol, of which she was given as much as 750,000 international units in three days, without effect on her blood calcium level. The only response to these high doses was a shift in her calcium excretion from feces to urine, indicating an increased absorption of calcium from the bowel. The storage or liberation of calcium in the bones was not affected. However, this cannot be said to be definitely abnormal in spite of the big doses, because C. I. Reed³¹ also did not get constant changes in blood levels from similar doses, but it is suggestive evidence confirmatory of that obtained with parathyroid extract. All that can be said of its effect on radium excretion is that this remained at the higher levels (table 2) established by the previous therapy. In summary, one may say that the methods of therapy which we used did increase the rate of radium excretion but the amount of radium which was withdrawn in this advanced case was insufficient to definitely lower the determinations of total stored radium in the body. In this regard the results agree with our first case and with the conclusions of Craver and Schlundt.¹¹

Is Radium as Easily Excreted as Calcium? It would be of interest to know whether the radium which is excreted corresponds with its relative ratio to calcium in bone, in order to determine whether therapy is more efficient in eliminating either the normal body constituent, calcium, or the abnormal radium. What one wants to know is the Ca/Ra ratio in the bones as compared to the excreta. The ratio as it appears in the excreta may be estimated from two groups of periods during a constant low calcium diet, in which the excretion of *extra* calcium and radium must come from the bones. If one compares the metabolic periods 5 to 10 with periods 18 to 21, in this case, one finds an increased calcium of 0.43 gram and radium excretion of 4.7×10^{-9} gram per period. From our calcium analyses of bone (0.233 gram of calcium per gram of dried bone), 0.4 gram of calcium represents approximately 1.7 grams of bone, which would indicate that this patient had an approximate radium content of 2.8×10^{-9} gram per gram of bone.

The radium concentration in the bones of this case can be estimated in three other ways. (1) By actual analysis of two bone samples, which were necrotic trabeculae spontaneously extruded from her jaw, we found 196

and 13.6×10^{-9} gram of radium and 0.212 and 0.230 gram of calcium per gram of bone

Calculating from this ratio, the actual increase in radium excretion during therapy is about one-fifth that which one would expect from the increase in calcium excretion. However, it has been shown that bone areas vary distinctly in their radium content and the mere fact that this bone was composed of trabeculae and had been killed justifies the assumption that it was relatively high in radium content. (2) The average radium in bone may be estimated, however, from the known radium stored in them. If one assumes the bones to be 16 per cent of the total body weight (53 kg), and, knowing the total radium stored (18×10^{-6} gram), one obtains the average figure of only 2.1×10^{-9} gram of radium per gram of bone. (3) The average bone radium may be calculated from comparison with another case, in whom total radium and actual bone analyses were obtained. In this case (C I), who had approximately $5 (\pm 1) \times 10^{-6}$ gram of radium in her body, the average analysis of five bone samples (table 3) gave 1.53×10^{-9} grams of radium and 239 gram of calcium per gram of bone. By correcting this ratio for the greater total radium storage of our patient 2 (E C) the average radium content of her bones would be 5.4×10^{-9} grams of radium per gram of bone. With calculations as crude as these, it appears that this figure roughly corresponds with the calculation of bone radium concentration obtained from the excreta and from calculation 2 above. These results, and similar calculations on patient 1, suggest that excreted and stored Ca/Ra ratio roughly correspond. The conclusions may, therefore, be drawn that the methods employed here are not more efficient in extracting radium than in extracting calcium from bone. It is more likely that they are both excreted in their relative proportion in the body—though possibly the calcium is slightly more easily mobilized.

Patient 3 (R L) was a physicist who had inhaled a very small quantity of radium only seven weeks before admission to the hospital. The radium storage when he started the metabolic studies represented only $0.6 (\pm 0.1) \times 10^{-6}$ gram of radium, yet this patient who had only about $\frac{1}{25}$ of the radium present in the other two patients was excreting radium at a much more rapid rate than were they. During the first period on metabolic regime, he excreted 1 per cent of his stored radium per day. This agrees with Schlundt's observations that the early excretion of radium is at a rapid rate in comparison to the excretion after several years.

The rate of radium excretion was obviously falling very rapidly before medication was started, a decrease which one would expect to progressively

continue The medication which we were able to give this patient was never large in amount and could be increased only slowly because of his sensitive, nervous make-up The result of the medication was to raise his blood calcium approximately 1 milligram, but we did not produce an acidosis inasmuch as the CO_2 content of his blood at the end of treatment was 22.3 millimeters per liter (low normal equals 25 millimeters) and the pH of his blood at that time was 7.4*. We, therefore, must assume that the therapy that this patient received was only moderate, and the effect on his radium excretion was to prevent a further decrease and, in fact, to initiate a slight increase in excretion (table 4)

When one considers the very moderate effect on the *calcium* excretion produced by medication and the very low Ra:Ca ratio in the bones (because of the small amount of stored radium) one should expect that the increase in radium excretion would be negligible As a matter of fact, if the reasonable assumption is made that the continued fall of radium excretion seen in the control periods would be progressive, then the effect of therapy on the radium excretion is striking and of a far greater magnitude than that found in the chronic cases This is further brought out by the markedly reduced excretion found approximately three months later, when the total radium content of his body had fallen to so low a level that it could not be quantitatively measured from gamma ray observations

Alveolar Air and Blood Concentrations Samples of normally expired air were obtained from all three of the patients at various times The numerical results are given in table 5

All radium slowly disintegrates spontaneously into the radioactive gas, radon, which has a half-value period of 3.8 days It is noteworthy that in each of the cases studied about 45 per cent of the total radon produced by the decay of stored radium escapes continuously from the body through the lungs This fact indicates the intimate nature of the contact between the circulating blood and the stored radium (which is located almost exclusively in the bones) Specimens of approximately alveolar air were also collected and analyzed for radon The technic of these collections and analyses has been previously described¹⁶ Table 5 shows that the radon concentration in the alveolar air is about two or three times that of normal expired air As one would expect, there is no significant change in the breath radon values during the course of medication No therapy would affect the production of radon, and its blood concentration and excretion by lung would be dependent upon the various gas laws

It naturally becomes of interest to determine the radium content of the blood The radium analytical technics are sufficiently delicate to permit approximate analyses of 5 c.c. of blood, though somewhat erratic values of blood radium were obtained From a series of analyses, there seems to be slightly less radium in the red blood cells than in the serum The blood of patient 2 (E.C.) was repeatedly analyzed and showed a mean value of the

* We take this occasion to thank Professor Baird Hastings for these analyses

order of 1×10^{-12} gram of radium per c c of blood Assuming a total volume of 5 liters of blood this is 5×10^{-9} gram of radium in the blood, or only about 0.03 per cent of her total body radium (18 micrograms)

TABLE V

Even knowledge of the approximate order of magnitude of the average radium concentration in the blood allows us to make several interesting calculations. Blood specimens taken from patient 2 (E. C.) during period 24 show an average of 0.95×10^{-12} gram of radium per c c of blood. This was a period of relatively low urinary radium output, but will serve for calculation. The kidneys eliminated 0.04×10^{-9} gram of radium per day during this period. As the blood supply to the kidneys is at least 500 liters per day,³² the blood stream carried an equivalent of $5 \times 10^5 \times 0.95 \times 10^{-12} = 5 \times 10^{-7}$ gram of radium, therefore, less than 0.01 per cent was removed continuously from the blood stream and eliminated from the body. Only about 1 per cent of the radium in the blood stream at any one time was removed per day. This computation emphasizes the relative ineffectiveness

of the kidneys in removing radium (and possibly other heavy metals) from the blood stream

During this period 24, the fecal elimination was 2.5×10^{-9} gram of radium per day, or 60 times the urinary elimination. Considering the vastly greater blood supply to the liver and gut we can say that the overall permeability of these organs to radium appears to be of the same rough order of magnitude as for the kidney. During period 18, the blood radium averaged 0.5×10^{-12} gram of radium per c.c., while the fecal elimination was 3.5×10^{-9} gram of radium per day. Here a similar calculation shows the daily elimination to be slightly greater than the total blood radium content at any moment of the day. These rough approximations suggest that it is less difficult to get radium out of the bone and into the blood stream than it is to get radium out of the blood stream and into the excreta.

DISCUSSION

From these observations, one may get a fairly clear-cut picture of what happens in radium poisoning. In the acute stage, during the first few months after exposure, the radium is scattered through the body and obviously more loosely held than later, and is therefore excreted at a far more rapid rate. In the later stages the bones hold onto the radium more tightly than at first. From the observations of Calhoun, et al.,²³ it is obvious that soon after heavy metals have been absorbed the trabeculae of bones have a relatively high concentration to that present in the cortex, while as time goes on there develops a more even distribution. Due to the relatively great amount of cortex, it is obvious that the greater proportion of radium is eventually stored in this part of bone. Inasmuch as it has been shown that the trabeculae are readily available for mobilization, and inasmuch as the radium is at first widely distributed in the organism, this gives a partial explanation of the relatively large liberation in the early weeks. As time goes on, it is to be expected that the cells should be injured or even killed in the area where radium is stored, and that the bones would respond less effectively to medication directed toward influencing their metabolism. In the patients we have studied, however, there has been a definite response to such medication, though in these chronic cases this has not been of a magnitude to greatly influence the total radium stored. Yet in spite of this relatively small percentage rise of radium excretion, a dramatic recovery from bone necrosis followed therapy in one of the patients (Patient 1 (M. H.)). Whether this was a matter of chance will remain a problem until further accumulation of evidence. It is obvious that such an improvement is only apt to occur when patients are treated relatively early before bone cells may be sufficiently injured so that recovery cannot take place. It remains for further studies to show whether this clinical improvement in this late case was due to a redistribution of radium in the bones, by largely dissolving trabeculae such as surround the teeth.

CONCLUSIONS

Radium stored in the body is analogous to lead in distribution, mode of excretion, and relationship to calcium metabolism

When radium is absorbed before the union of bone epiphyses, this area of bone may appear abnormal

Most stored radium (more than 90 per cent) is eliminated in the feces even when the excretion is artificially stimulated

The bile contains radium, and therefore also appears to be a route of excretion

Radium excretion can be elevated four to eight fold by decalcifying therapy, but this still does not greatly reduce the total stores of radium in the body

The response of radium excretion to deleading therapy is slower than is the calcium response. The excretion rate rises slowly and is prolonged after therapy has stopped. The probable mechanism involved is discussed

The administration of magnesium gluconate appears to elevate radium excretion just as it affects calcium excretion

One case of advanced, chronic radium poisoning gave no response to large amounts of parathyroid extract, possibly because of damage to bone cells. The only response to activated ergosterol was to maintain a high level of radium excretion. Nevertheless, storage of calcium was still accomplished when a high calcium diet was administered

The rate of increased radium and calcium excretion, after the effects of therapy have been established, indicates that the efficiency of treatment is roughly the same for both, and it is probable that the average Ca:Ra ratio present in bone is approximately similar to that of the stored metals excreted

CASE HISTORIES

Patient 1 (M. H.) was a woman of 54. About 10 years before entrance she was given an unknown amount of radium intravenously for arthritis. Neither the number of injections nor the amount of radium can be ascertained. There is also the possibility that she drank a little "radium water." Thirty-two months before entrance, she had a left lower molar tooth removed, and after this her jaw never healed and subsequently had to be repeatedly curetted. A year later the few remaining teeth were removed, and the entire left lower jaw was curetted. This continued not to heal, and spicules of bone continued to appear until eight months before entrance, when stored radium was found but was not quantitatively determined. At that time she had six weeks' treatment with low calcium diet and daily oral administration of six grams of ammonium chloride and two grains of Armour's thyroid extract. After this treatment she returned to a high calcium diet. The chronic area in her jaw promptly improved, but was still draining in November 1934, when she entered the hospital for further treatment.

Physical examination was essentially negative except for necrosis of her jaw. She remained in the hospital until December 15 on therapy outlined in her table then returned home and remained on a low calcium diet, but without further medication until she was readmitted to the hospital on January 16, 1935. She was then given a high calcium diet, and in addition 8 grams of calcium gluconate daily, and the last control observation was then made.

A roentgen-ray of the jaw on January 30, 1935, showed considerable filling in with new bone which had occurred within the last eight weeks. Since this time her jaw has progressively improved. The sinuses stopped draining within two months, and for the last year the bone has had a practically normal appearance.

All the laboratory results were normal except that the red blood count was 3,900,000, though the hemoglobin was 91 per cent (Sahli). The plasma phosphatase on entrance was 0.12 Kay units (average normal value 0.15), and 0.20 Kay units after therapy was discontinued.

Patient 2 (E. C.) was a 30-year-old woman, who entered the hospital complaining of painful feet on walking. Just 14 years ago, when she was 16 years old, this young lady began painting luminous numbers on watch dials, and since then she has been almost continuously employed in the same work. For the first seven years the brush was touched to the lips to point it for the delicate work. For the past seven years the painting has been done with glass pens, and under far better hygienic conditions. Five years ago, she began to notice aching in the right ankle when walking, and two years ago the right foot was put into a plaster jacket for one year. One and one-half years ago, the pain started in the left hip. Four years ago she first had trouble with her jaw. It became swollen and three teeth were subsequently pulled, and the upper jaw remained swollen for several months thereafter. It did not really subside for six months, with continuous drainage since that time in both upper and lower jaw. These sinuses have produced very little pain. Five months ago a tooth dropped out of the right upper jaw spontaneously. The patient's diet was adequate but she rarely drank milk. About six months before entrance, radium was first detected in her body.

Her physical examination appeared normal except the jaw which showed a small area of exposed bone in the right upper area, and also a loose piece of cancellous bone between teeth in the left upper jaw. There was a very small draining sinus in the left upper jaw.

Four days after her admission she lost a small piece of cancellous bone from the right jaw. The second piece, which was very loose on entrance, came away after a month in the hospital, and the third very small piece from the same area came away three weeks later. There did not seem to be any other loose bone about her teeth. The bone pains practically disappeared after she had been in the hospital several weeks, but before her discharge they returned in about the same intensity as on entrance.

Her stay in the hospital was without untoward incidence, except that on the forty-second day after admission she complained of right-sided abdominal pain, a little nausea, and loss of appetite. This was possibly a mild attack of appendicitis, but it promptly subsided without therapy. Her study was continued for 18 weeks, and she left the hospital in excellent condition.

Extensive laboratory studies were all negative save for an anemia of 3,600,000 with 63 per cent hemoglobin (Sahli) which developed while she was in the hospital. This was completely relieved within a month following iron and liver therapy. There were a surprising number of stippled cells seen in all of her blood smears, sometimes more than one in each field. The roentgen-rays of bones showed interesting small areas of rarefaction and eburnation scattered through the trabeculae. There was distinct pathological union of the epiphyses of shoulders and hips, indicating a definite radium influence before epiphyseal closure. The treatment and pertinent laboratory studies are shown in the table. Plasma phosphatase was consistently low throughout her stay in the hospital, being 0.06, 0.07, and 0.06 Kay units.

Patient 3 (R. L.) was a physicist (male), 54 years of age. Fifty-three days before entrance he was sealing a mixture of 100 milligrams radium chloride and 5 grams of beryllium powder into a steel tube when the plug was blown off this tube and some of the mixture filled the room. Some particles settled on his face. While still in the laboratory he washed himself carefully, but it is probable that he breathed

some of the dust at this time. He promptly thereafter had his eyes and teeth carefully cleaned. There have been no symptoms following this exposure to radium. The patient is well except that he had had indigestion for several years prior to five years ago, when an appendectomy was performed. Since then his digestion has improved.

Physical examination was not abnormal.

The patient was maintained on a high calcium diet for three periods, during which time he was allowed to eat what he pleased, except for a daily ration of one quart of milk. He was then put on a carefully weighed low calcium diet, and started at the same time on 3 grams of ammonium chloride a day. The subsequent medication is indicated on his table. Until his discharge 30 days after entrance, the patient continued on a very moderate amount of medication because he was afraid his old indigestion would be reprecipitated, and therefore only mild doses of medication could be used. Careful laboratory studies were all normal. He had no anemia, and his blood phosphatase determination was also normal, being 0.14 Kay units on entrance.

He then went to Europe for the summer, remaining on a rather low calcium diet. He had excellent health all summer and spent much of his time mountain climbing. After 12 weeks he returned to the hospital where he remained for seven days. During this period of observation his radium excretion was measured for control purposes, while he was given a full diet with added milk. It is interesting that he had gained 11 pounds in the 10 weeks between the two hospital admissions.

GONORRHEAL ENDOCARDITIS WITH BILATERAL PAROTITIS AND TOXIC JAUNDICE AS ADDITIONAL COMPLICATIONS ⁺

By WALTER R. STEINER, M.D., and LORTUS L. WALTON, M.D.,
Hartford, Connecticut

THE first case of gonorrheal endocarditis in which the gonococcus was grown by blood culture, as well as by cultures from thrombi on the heart valves, was reported by Drs. Thayer and Blumer¹ in 1896, in the Johns Hopkins Hospital Bulletin. Previously, there had been a few cases in which the organism found in endocarditis was morphologically and tinctorially characteristic of the gonococcus. It was also intracellular in the smear made at autopsy. Since then, cases presenting this complication in gonorrhea have multiplied, until in 1932 Hoffman and Taggart,² after a careful review of Thayer's list³ of reported cases, rejected six of them and added seven more, including one of their own, so that at that time 76 instances of this condition were found to have been reported. More recently, additional cases have been reported, for Eakin⁴ in 1934 found two more, increasing the number to 78, and in the years that have followed more have been published, so that now about 150 reputed cases have been recorded. In 1934, Stone,⁵ after a careful analysis of all of the reported cases, divided them into four groups totalling 123 cases. He allotted to the first, or proved group, 85 cases, to the second, or presumptive group, 12 cases, to the third, or probable group, 15 cases, and finally to the fourth, or possible group, 11 cases. In this list he could find only 34 cases in which the gonococcus had been grown by blood culture, although in 71 of the 112 cases falling within the first three groups, blood cultures had been made and in 14 of them, where the gonococcus had not been found by blood culture it had been grown from the heart's blood, vegetations, joint, pericardial or pleural fluid. Thirteen additional cases⁶ have yielded positive blood cultures in the years that have intervened since then. Of course some cases of this condition have existed, and do now exist, from whose blood culture the gonococcus has never been isolated, although numerous attempts have been made to grow it. On the other hand, the organism has been grown by blood culture in cases of bacteremia in which there has been no demonstrable cardiac involvement. Tabbutt,⁷ for example, has reported two such cases. Jenkins,⁸ O'Brien and Bancker,⁹ Wheeler and Cornell,¹⁰ Rubenstone and Israel,¹¹ Fillee,¹² and Friedberg¹³ also have reported similar cases with recovery. Others probably exist in the literature upon this subject. The

* Received for publication August 14, 1937

recoveries from this condition have been few, but they are not as rare as was formerly supposed. Stone¹⁴ lists six of them, and Newman¹⁵ adds nine to their number. Since then, two more have been reported. Kolle and Hetsch¹⁶ were of the opinion that only 0.7 per cent of all the patients who acquired gonorrhea developed gonococcal septicemia. The portal of entrance of the organism in every case is the genito-urinary tract, although occasionally the primary focus cannot be discovered. The history of our case is as follows:

CASE REPORT

Gonorrheal cervicitis two weeks following exposure, chills and evidence of cardiac involvement two months later followed in two weeks by recovery of the gonococcus by blood culture after five negative results, typical course of endocarditis with subsequent onset of bilateral parotitis and terminal toxic jaundice

S. V., female, aged 17, worker in the tobacco fields, was admitted to the Hartford Hospital on the Gynecological Service on August 23, 1934, complaining of pain in her right side. This symptom appeared 10 days before, but subsided quickly only to appear again the day of her entrance into the Hospital with nausea but not vomiting. She thinks she had some additional pain, however, at her June period, and may have had some fever on that occasion. Four months ago, about the middle of May, while returning with her partner from a dance, she was violently attacked by him and raped. Fourteen days subsequently a profuse yellowish vaginal discharge was noted. Her period, after the attack, came on two days later and continued for five days. Previously it had always been regular every 28 days, and of two to three days' duration. Now she is a few days over-due, and is much concerned about it, fearing pregnancy. She thinks that in the past month she has not felt as well as she normally does, and that occasionally she has had sensations of chilliness and fever. Her family history and past history were negative.

On admission she was found to be a well developed and well nourished woman, with face somewhat flushed, she was lying comfortably in bed and did not seem ill save for her flushed facial expression, the lungs were negative on examination, while the heart, though not enlarged and with sounds of normal relative intensity, showed at the base in the pulmonic area, a slight blowing systolic murmur. The abdomen was negative save for slight tenderness in the right lower quadrant. By vaginal examination the urethral orifice showed slight reddening with the presence of a slight, milky discharge, while from the vagina a profuse, yellowish discharge was noted. Bi-manual examination revealed slight tenderness in the right lateral fornix. Her temperature on admission was 101.2°, and her leukocyte count 25,200, with the polymorphonuclears 95 per cent and the mononuclears 5 per cent.

On August 27, Dr. Howe made the following note: "Nulliparous type of introitus, profuse thick flocculent discharge, Skene's ducts injected and a thin, milky discharge is readily expressed from them, smears taken. Cervix shows a slight degree of erosion about the external os, otherwise negative. Fundus normal in size and consistency, freely movable with some tenderness, no masses palpated, but patient is acutely tender on the right side. Impression: Acute skenitis, vaginitis, urethritis and endometritis probably Neisserian in origin. Treatment: Rest and expectant treatment." Twelve days later he noted the examination showed no change, save that the tenderness had disappeared but the local condition was unchanged in spite of the daily douches and routine treatment. A blood culture was taken on September 7, and I was asked to see her five days later.

Being on the Medical Service, I thought as her heart and lungs were normal that her pelvic condition might account for the temperature, and advised that she

remain at present on the Gynecological Service. I suggested further blood cultures, as well as a search for malarial organisms. The soft, systolic murmur which had existed at the pulmonic area since admission, did not appear to have any especial significance. Her temperature since admission had shown marked remissions, resembling closely a picket-fence. I advised at a second consultation on September 17, that a culture be taken at the height of her temperature, and again at its lowest point. A cystoscopic examination was performed the next day with negative results. On September 20 she developed marked systolic and diastolic murmurs at the base in the

FIG 1 Pulmonic valves with vegetations

pulmonic area. Convinced that the septic process was localizing itself on the pulmonic valve, although the blood cultures had been uniformly negative, I accepted her for transfer to my Medical Ward. In spite of five negative cultures, I ordered one of my interns to take another culture, plant it at the bedside and proceed at once with it to the Laboratory. We were shortly thereafter rewarded with the report of a gram-negative diplococcus being found, which was culturally and morphologically typical of *Neisseria gonorrhoeae*. In the culture from which it was isolated there were approximately 9 colonies per c c of blood. Some weeks later, on October 24, another successful blood culture was obtained with approximately 80 colonies per c c of blood. The patient was given twice weekly transfusions of 250 c c of blood, with no improvement (14 in all). The febrile excursions became less marked, but the chills, which were first noted on September 20, continued. After this first one, they were daily for three days, then after a five day interval, daily for seven days, and subsequently after one or several days interval continued daily until her death. A severe and intractable cystitis developed about October 15, which nothing seemed to

relieve About this time she complained of pain in the left upper quadrant, but the spleen was not palpable until November 9 Eleven days later a bilateral parotitis was observed, which quickly responded to cold applications The patient now became increasingly somnolent, was often irrational and was at times a difficult nursing problem The murmurs at the pulmonic area became much more pronounced, she developed a toxic jaundice with bile in her urine and died on November 28

Laboratory Data *Urine* August 24, 1934 Yellow, clear, no sediment, acid, specific gravity 1.010 Albumin, none, sugar, none, microscopically, a few white blood corpuscles A month later a few hyaline and granular casts were seen, the white blood corpuscles showed an increase and some red blood corpuscles were noted The white blood corpuscles soon became more numerous and showed distinct evidences of cystitis by their numbers, singly and in clumps The specific gravity varied from 1.009 to 1.025 Bile was found in the urine on November 25, 1934 The non-protein nitrogen on October 10 was 33 mg per cent but by November 21, it had risen to 70 mg per cent *Blood* The leukocyte count on entrance has been given By September 3, it had fallen to 9,100, while the differential count showed Polymorphonuclears 79 per cent, lymphocytes 19 per cent, mononuclears 2 per cent On September 14, the hemoglobin was 60 per cent and the red blood corpuscles 3,650,000 A week later the hemoglobin had fallen to 56 per cent, while the white blood count was 13,450, with the following differential count Polymorphonuclears 92 per cent, lymphocytes 6 per cent, mononuclears 2 per cent There was slight anisocytosis present In the next month, on October 16, there was not much change save in the white blood count which had risen to 19,200 The hemoglobin and red blood corpuscles showed slight change until the end, but the white blood count fell on November 10 to 10,900

Electrocardiograms Were made on September 26 and October 8 Dr Robert S Starr, our cardiologist, made the report on both of them The first showed a pulse rate of 105 per minute, with normal rhythm, P R interval 0.14 second Impression a normal E K G In the second, the only difference was in an increased pulse rate, it being 120 per minute

Cultures *Blood* Four blood cultures were taken on September 7, 13, 17, 19 and 21 with negative results Finally, one was taken on September 28 and brought quickly to the laboratory It showed a gram-negative diplococcus culturally and morphologically typical of *Neisseria gonorrhoeae*, with approximately nine colonies per c c of blood, while another on October 18, showed a similar organism in larger numbers, 80 colonies being seen approximately per c c of blood

Urine The urine showed on September 17 the *Staphylococcus pyogenes aureus*, the *Streptococcus hemolyticus* and non-hemolyticus and the *B. fecalis alkaligenes*, but on October 19, only the *Staphylococcus pyogenes aureus* and the *Streptococcus non-hemolyticus* were grown Five smears from the cervix and urethra were taken and were negative for gonococci

An autopsy was performed by Dr Perry Hough two hours after death The anatomical diagnosis was *gonorrheal cervicitis, gonococcus septicemia, acute pulmonary gonococcus vegetative endocarditis, acute splenic tumor, chronic passive congestion of the kidneys and jaundice*

There was a marked icterus of the skin and conjunctivae, besides small, irregular petechiae which were scattered profusely in the skin over the upper and lower extremities The changes in the lungs, heart, spleen and kidneys merit full description, and were as follows

Lungs Right 350 gm Left 300 gm There are no adhesions and no appreciable amount of fluid in the pleural cavity On section there is practically no edema or congestion Scattered throughout both lungs, especially in the lower lobe, there are a few dark, nodular areas, appearing to be small areas of infarction, and in the base of the right lower lobe there is one wedge shaped area of infarction just outside of the

periphery about $1\frac{1}{2}$ cm in diameter. There is no pneumonic consolidation. The bronchi and peribronchial lymph nodes appear normal.

Heart 240 gm. There are about 80 c.c. of cloudy, amber fluid within the pericardial cavity. The right ventricular wall is 4 mm in thickness, the left ventricular wall is 15 mm, and there is a marked dilatation of the right side of the heart with less dilatation of the left. The myocardium everywhere appears grossly normal. The aortic, mitral and tricuspid valves are grossly normal. The leaflets are thin, and pellucid, with no vegetations. The pulmonic valve is markedly involved with large, varicose, buff-colored, friable vegetations extending completely around the ring, involving all of the leaflets. The largest averages 2 cm in diameter and is attached by a broad pedicle. There are smaller, nodular, similar vegetations extending for about 2 cm along the pulmonary artery and scattered diffusely over the endocardial surface of the right ventricle in the region of the pulmonic valve. The coronary arteries are thin and patent throughout.

Spleen Tremendously enlarged, weighing 1100 gm and extending 9 to 10 cm below the left costal margin. Splenic notch is preserved. On section the organ is moderately firm and dark red in color. The malpighian corpuscles are rather indistinct and at one point toward the lower pole there is a small, somewhat lighter area than the surrounding tissue of slightly increased density, possibly representing a small infarct. It covers a diameter of approximately 1 cm.

Kidneys Weight together, 420 gm. Capsule thin, and strips easily, leaving a smooth cortical surface over which there is scattered diffusely tiny areas of hemorrhage, averaging less than 1 mm in diameter. On section the cortex is swollen. Tiny hemorrhages are seen throughout the cortical tissue and the normal striations are somewhat indistinct. Renal pelves and ureters are grossly normal, as is the bladder.

Genitalia Negative, save for a few tiny cysts in the upper and posterior cul-de-sac of the vagina, averaging 1 mm in diameter. The tissue is here moderately indurated.

Microscopic Examination

Lungs Microscopically normal except for the areas of infarction mentioned in the gross. These microscopically appear to be typical infarcts with degeneration of the alveolar walls, the alveolar spaces being engorged with blood cells, serum and old blood pigment. In one section, apparently from one of the old infarcts, there is complete necrosis. Around the margin there are a few polymorphonuclear leukocytes, and interspersed among these there is a suggestion of bacteria having a coccus form but not being definitely biscuit-shaped diplococci.

Heart Section of the heart valve shows superimposed upon it a vegetation consisting of well organized thrombus in which many proliferating fibroblasts are seen along with a few polymorphonuclear leukocytes and a moderate small round cell infiltration. Special stain reveals through the vegetation colonies and isolated groups of gram-negative diplococci microscopically typical of gonococci.

Liver Essentially negative.

Spleen Splenic sinuses are engorged with red blood cells and throughout there is an accumulation of brown pigment, apparently old blood pigment. There is no increase in the reticulum elements. The malpighian corpuscles are rather small and somewhat distorted. No areas of infarction are seen microscopically.

Kidneys The tiny hemorrhages mentioned in the gross appear microscopically to be only dilated capillaries engorged with red blood cells and old red blood pigment. There is no actual hemorrhagic extravasation in the renal parenchyma. There is cloudy swelling of the tubular epithelium. The glomeruli everywhere appear normal. No interstitial fibrosis or red cell infiltration. A few tubules, however, contain casts composed chiefly of degenerated blood. No gonococci found by postmortem culture.

Genitalia No evidence of acute inflammatory reaction in the sections from the

vagina The epithelium in one portion has been denuded apparently at the site of one of the small cysts mentioned in the gross Underlying the epithelium there is a slight infiltration with small, round cells Cervix Presents a similar picture The epithelium is everywhere intact, but beneath this there is a definite layer of chronic inflammatory reaction, consisting essentially of small round cells with a slight degree of fibrosis Salpinx Negative

SUMMARY AND COMMENT

Our patient was a woman, aged 17 years, who developed an acute cervicitis two weeks after the exposure to infection, an endocarditis followed after an indefinite period, followed in turn by a bi-lateral parotitis and a terminal toxic jaundice The blood culture was positive and the pulmonary valve was found to be involved at autopsy Since this case was seen, two other methods for the treatment of gonorrhea have been utilized, namely artificial fever¹⁷ and the drug sulphanilamide Both seem to offer something in the way of treatment

Dr W S Thayer¹⁸ has shown that the aortic valve is most commonly implicated in this disease, and that the pulmonary valve is more commonly affected in this variety of endocarditis than in the sub-acute type Although gonorrheal endocarditis generally follows an arthritis, a study of this case shows that this latter complication was absent An initial chill probably ushered in the heart involvement The bilateral parotitis which occurred later in the disease, was probably due to bacteria which were secondary invaders Jaundice is a rather unusual development and probably had a toxic etiology It was seen in Silvestrini's case¹⁹ which recovered, and in Blumer and Nesbit's fatal case²⁰ where it was associated with a hepatitis

Recently Lichtman²¹ has reported a case in the *Journal* of the Mt Sinai Hospital in which he considers that the jaundice probably resulted from rapid and extensive blood destruction, overactivity of the reticulo-endothelial system and liver cell damage due to bacterial toxins The presence of bilirubin in the urine indicates a regurgitative type of jaundice associated with hepato-cellular necrosis Lichtman refers to a former article he wrote in conjunction with Kugel²² on "Factors Causing Clinical Jaundice in Heart Disease" He also gives a reference to Popper and Wiedman's interesting article²³ on "Gonotoxic Icterus" In our case, the jaundice appears to be due to the effect of the gonotoxin on the parenchyma of the liver The red blood corpuscles remained about stationary at 3,500,000 Popper and Wiedman consider the jaundice caused by this microorganism generally similar to the simple catarrhal type, although occasionally cases are found resulting finally in acute yellow atrophy of the liver

The difficulty of cultivating gonococci has caused the number of these cases reported to be comparatively few in their relation to the total published number of cases presenting this complication A positive ante- or post-mortem culture is, however, the only absolute criterion for a diagnosis A

history of gonorrhea followed by a mono-articular arthritis which is in turn followed by an endocarditis offers strong presumptive evidence of the endocarditis being gonorrheal in origin. Indeed it would do so even if a mono-articular arthritis had not existed and even though the blood cultures were negative.

THE NON-OPERATIVE TREATMENT OF HYPERTHYROIDISM *

By DR. HELMUT DENNIG, *University of Berlin*

EVEN though, in the present day treatment of hyperthyroidism, operation is more frequently resorted to than is conservative treatment, nevertheless the latter still has a wide field of usefulness which is well worth reviewing. In Germany, opinion is still very much divided concerning the value of non-operative treatment. There are clinics where patients are seldom brought to operation and others which use only operative treatment. The majority probably occupy a middle ground. In this connection, I may refer to the questionnaire which we presented to several clinics a year ago.¹

A great many misunderstandings have arisen because of the fact that nomenclature is not uniform. Many authors distinguish special forms of the disease, which are, for example, termed "hyperthyroidism" as opposed to "complete Basedow." In America the toxic adenoma plays a special rôle which finds little or no recognition in Germany. It is particularly difficult to define the very mild cases, the transitions between "vegetative stigmatization" to "mild Basedow" or "Basedowoid," etc. In the presence of such confusion, statistics concerning the results of treatment by various authors can hardly be compared. The best conclusions can be drawn if, in the same clinic, some patients are referred for operation and a similar number are reserved for conservative treatment, after which the end results may be compared. My personal experience has such a basis.

We do not deny the possibility that there may be certain special forms of the disease—for example, those of pituitary origin or where the underlying cause is perhaps not an excessive amount of thyroxin, but another unknown toxic substance. The actual proof of the existence of such special forms is, however, not assured. It seems likely to me that in the majority of cases there are no qualitative differences, but only quantitative ones which are of significance. If the illness is frequently variable in form, we need not assume variable noxae, but simply that the same noxa results in different reactions in individuals of different makeups. This is also true in other diseases. In any case, it seems to me entirely satisfactory in everyday practice to speak of mild, moderate and severe forms. Here, the clinical picture, as a whole, must be the deciding factor. Of all the symptoms, the increase in the basal metabolism is probably still the best measuring stick, but it would be unwise to let this be the sole criterion. Cardiac disturbances

* Received for publication August 21, 1937.
Translation by Robert W. Buck, M.D.

may be of much greater significance. The various symptoms are different, too, in different communities. In Berlin, for example, we see quite a number of patients who have no exophthalmos and little or no enlargement of the thyroid gland, so that the diagnosis is often not made.

One of the first needs which must be met is *psychic treatment*, although I question whether excitement or fright plays such a decisive rôle in the origin of hyperthyroidism as is often assumed. Nevertheless, it is certain that they are very significant in the further progression of the disease. Removal of the patient from the cares of daily life or freeing him from oppressive psychic conflict—for example, by conversation with a good physician—may cause apparent improvement. In this sense, a change in environment often has a good effect, as we see when the patients are brought to a hospital from a sanatorium. Perhaps, in this connection, certain *climatic factors* may be of significance, regions of moderately high elevation being favored. At any rate, certain sanatoria enjoy an especially good reputation, not entirely without reason, and specialize to a certain extent in the treatment of hyperthyroidism. *Physical rest* shares with mental reassurance the task of conserving calories, thereby combating emaciation in the presence of the elevated metabolism. On this account, a great deal of time in bed or even strict bed rest is indicated, at least for a few weeks.

For the same reason, the diet must be rich in calories, disregarding the unusual cases of obese patients with hyperthyroidism. Most physicians prefer a diet poor in protein on the ground that protein elevates the basal metabolism because of its specific dynamic effect. I do not think we need worry too much about this. At any rate, our first concern must be the maintenance and stimulation of the appetite by giving a mixed diet which should be rich in vitamins as well. There are certain definite indications for the administration of vitamin. For example, vitamin "A" is supposed to have a definite effect against hyperthyroidism. Wendt² has reported improvement with large doses, I, myself, have not as yet been able to arrive at any definite conclusion in this respect. However, this subject is still open.

Not a few patients have a tendency to *diarrhea*. This is in part the expression of a nervous acceleration of intestinal peristalsis and in part the result of a hypoacidity or anacidity of the gastric juice which is fairly common in hyperthyroidism. In every case of diarrhea, a fractional gastric analysis should be made because, in these cases, very definite improvement may be achieved by a rather careful diet, together with the administration of hydrochloric acid (e.g., acid hydrochloric non-dilut, pepsin sicc, 40.0, aquae q.s. ad 200), 1 teaspoonful in a glass of water, $\frac{1}{3}$ of which is to be taken through a glass tube before, during and after the meal.

Insulin and glucose are often prescribed, since in animal experiments a definite antagonism between thyroxin and insulin has been demonstrated. The general effect, however, is only slight. Nevertheless, in the presence of marked emaciation and loss of appetite, a trial is justified. Increase in weight is, to be sure, for the most part attributable to water retention.

Physical and mental rest may be effectively supported by means of *medication*. We give either bromides or, better still, drugs of the barbituric acid series. Luminal has, in general, proved most satisfactory. The dosage, however, must be strictly adjusted to the individual's peculiarities—in many cases, very small doses suffice, perhaps 0.015 gram two or three times daily. Other patients require much more, perhaps as much as 0.05 gram morning and noon, together with 0.1 gram in the evening. If luminal results in drowsiness rather than sedation, prominal should be tried, which has a predominantly sedative effect, approximately double the above dosage may be given. A favorite old-fashioned remedy to improve the general condition is arsenic in practically any form.

A great many of the symptoms of hyperthyroidism rest upon an irritability of the sympathetic nervous system. *Ergotamine* may be regarded as a direct antidote which lowers the excitability of this system. As a matter of fact, many symptoms can be markedly influenced with this drug—those such as tachycardia, tremor and even exophthalmos. However, if sufficiently high doses are given over a prolonged period, the danger of ergotism and gangrene of the extremities is considerable. Further, ergotamine often causes nausea. As a result, I have quite given up its use.

Repeated attempts have been made to discover anti-substances in animal blood which will be effective against the action of thyroxin. In this group belong the old antithyreoidin of Moebius, derived from thyroidectomized sheep, or Blum's thyronorman. Although these investigations are very interesting—in animal experiments the substances seem to be quite effective—nevertheless, in my personal experience I have seen no important practical results. It is possible, however, that further progress may be made along these lines.

Much more effective than the above mentioned methods is *iodine treatment*. Although the pre-operative administration of iodine over short periods of time, as introduced by Plummer and Boothby in 1924, is now recognized throughout the whole world, the prolonged treatment, as advocated in 1920 by Neisser in Stettin, is still disputed. However, our experience during the last few years has also brought a good deal of enlightenment in this connection. This much is certain: treatment with iodine is an art demanding intuition and experience, without these, harm may result. However, in the hands of an experienced man who knows the limitations of the treatment, it is extraordinarily effective. As yet we know very little theoretically as to what happens when iodine is administered and on this account we have had to depend all the more on our experience. This shows us the following facts:

The optimal dose lies between 50 and 200 milligrams of iodine daily, within these limits, individual variations can and should be made. Nothing is to be gained by giving larger amounts. Indeed, a single larger dose may occasionally lead to acute exacerbation of symptoms. The manner of ad-

ministration of iodine is unimportant, only the amount of iodine given being significant, whether or not the iodine is given in organic or inorganic form. Thus, we have seen no difference between calcium iodide, sodium iodide, Lugol's solution, di-iodide thyrosin or sajodin, so long as the above mentioned dosage of iodine was maintained^{3,4}. Frequently, however, by changing the form of the preparations, some of the unpleasant by-effects, such as iodine coryza or iodine acne, may be controlled, however, these by-effects are rare and often must be accepted as part of the bargain.

The favorable effect of iodine occurs after two or three days, reaching its maximum in one or two weeks, the basal metabolism falls sharply, the pulse rate becomes slower and, not infrequently, a completely irregular pulse becomes regular again, tremor grows less, exophthalmos often diminishes, the restlessness disappears and there is a gain in body weight. The great question is only—for how long a period does this improvement persist? The surgeons believe that operation should be performed at the maximum point of this improvement, which is, no doubt, correct in the majority of cases, if operation is to be done in any case. If operation is not performed, however, and iodine is nevertheless continued, the favorable effect gradually diminishes, at least, there is no further continuation in the improvement. It is well to stop treatment from time to time—for example, to give iodine for eight to 14 days and then to stop it for three to five days and to constantly repeat this series. This may be continued over several months. I wish to say very definitely, however, that a complete cure is almost never attained by these methods. As soon as iodine is given up for a prolonged period of time, the old symptoms return, sometimes, indeed, more marked than before. Here lies the danger in iodine treatment. If we once begin to use iodine, we do not dare to stop it unless an improvement is obtained in some other fashion—i.e., either by operation or roentgen-radiation. Further, after a course of iodine of long duration, particularly if intervals of freedom have been observed, one can still operate. In this way, very sick patients may show a marked gain of weight in the course of a few weeks and may be operated upon while in much better general condition. Of particular significance is iodine treatment of long duration in association with roentgen-radiation, which will be discussed below. The good effect of radiation begins only after a number of weeks. During this period patients can be maintained temporarily in very good fashion by means of iodine, which may be given up when the roentgen-ray effect is apparent. This seems to me to be the principal value of long-continued iodine treatment.

There are only a few patients who do not respond to iodine and in practice a trial of its use can be made in the most widely different forms of hyperthyroidism. It has an especially favorable effect in those cases of hyperthyroidism which have been induced by iodine. Even these cases do not, as a rule, occur during the period that iodine is being given (as, for example, in anti-luetic treatment or in arteriosclerosis), but rather more especially

when the iodine is discontinued. It requires some courage to give iodine again if it is known that the condition was caused by giving iodine. But experience shows that we must have this courage and that the patients become much better if we give them iodine again. Then, by all means, however, cure must be effected by operation or radiation.

It is also very important to give iodine if a patient with hyperthyroidism is attacked by an infection or meets with an accident. In this way he can be carried through a dangerous period.

Roentgen-ray treatment is also the subject of controversy. Here, however, the limits of treatment and its indications are gradually becoming clear.* If a good roentgen therapist conducts the treatments, it is certainly even less dangerous than operation. Indeed, if radiation, as described above, is combined with intermittent iodine treatment, there is practically no mortality whatever to be considered. This is a great advantage which decisively determines the course of action for many patients and physicians. There are, however, very serious objections to this procedure. The number of complete cures is not nearly as large as with operation. If many authors, however, still deny that any good results follow roentgen-ray treatments, this can only be the result of insufficient experience or unsatisfactory technic. I am familiar with a whole series of severe cases which were completely cured after radiation, but, as a matter of fact, many complete failures also occur and one sees particularly often marked improvement, but no such complete cures as usually occur after operation. After a few months there may be recurrences. Often we can obtain further improvement after a new series of radiations, but the end result still remains less certain. A further objection is the long duration. As a rule, several weeks or often as much as three to five months elapse before the definite improvement begins. During this time very dangerous spontaneous exacerbation of the disease may occur and this is the principal reason why we demand simultaneous iodine treatment as above mentioned.

If no permanent results occur following radiation, not much time or money has been lost. It is possible, in spite of a widespread opinion, even then to operate without any special difficulty, if one has not waited too long. At any rate, I have seen a great number of patients who were operated upon several months after a course of radiation which was without result, and who were then cured.

The symptomatic treatment of *disturbances of circulation* demands

* My personal experiences are based upon patients in my ward, the iodine treatment of whom I have supervised and whose roentgen-ray treatment was undertaken in the wards of Dr. Muehlmann of Stettin and Prof. Frik of Berlin. As a rule, 10 roentgen-ray treatments were given with intervals between them of 8 to 10 days. After the fifth radiation, there was usually a rest of five weeks and the remaining five treatments were then given similarly to the ambulatory patients. A radiation of 185 roentgens, measured in air, 0.7 Cu half value layer over a large field including thyroid and thymus is given at a distance of 30 to 40 cm at each treatment so that in a period of ten to twelve weeks a total of approximately 1650 roentgens measured in air are given. The effective dosage in this area is not uniform but may probably be considered to be in the neighborhood of 1000 to 1100 roentgens measured in air.

special attention The simple tachycardia of hyperthyroidism, with its markedly short contractions of the heart, and *pulsus celer* is doubtless an unfavorable form of cardiac activity While in other cardiac conditions, digitalis slows the rapid pulse, here, for the most part, there is no clear-cut effect Only when definite circulatory failure with congestion of the liver and edema occur is it desirable to make use of digitalis As a rule, iodine, alone or in combination with digitalis, works much better Auricular fibrillation in hyperthyroidism is especially noteworthy It may be the expression of severe damage to the heart muscle, but frequently is only a transient symptom which is relatively easy to control in contrast to the auricular fibrillation caused by arteriosclerosis Auricular fibrillation occurs during periods of aggravation of the hyperthyroidism, as for example, during the first few days after thyroidectomy, and during periods of transitory improvement it may suddenly disappear Quite often the cardiac action becomes completely regular under iodine treatment, but as soon as iodine is omitted, the auricular fibrillation recurs The irregularity may also, for the most part, be corrected by means of quinidine or quinine, but, as is well known, the use of these drugs is not entirely without danger and should only be carried out by experienced persons with constant clinical observation

If, then, we search for indications for the various forms of treatment, we shall perhaps take the following position Very mild cases should perhaps not be treated at all, particularly not with iodine—they should be only watched These are the patients who have single mild symptoms, such as tachycardia, or vasomotor excitability with a tendency to profuse sweating, or a slight stare, etc Such cases have been designated vegetative neuroses or Basedow types No true disease is present, but they are on the borderline of normal For the most part, no true hyperthyroidism eventuates These people rather preserve their individual peculiarities throughout their lives

In the moderately severe cases, one has a choice between operation with a short period of pre-operative preparation with iodine and roentgen-ray treatment with prolonged iodine administration Operation is followed by a more rapid and certain effect Radiation is less dangerous, its effect is definitely slower and not so certain Therefore, one may decide in accordance with the courage and economic circumstances of the individual We strongly advise operation only in acute hyperthyroidism of only a few weeks or months duration, since the outlook here is especially favorable In older and more severe cases, we are inclined, on the other hand, to try radiation first Then, if operation is here resorted to, it is often desirable to give iodine not only during the short pre-operative period, but also intermittently over a longer period of time, together with all other symptomatic measures that can be used in order to improve the general condition

If, however, conservative treatment results in no cure after a few months, we unconditionally advise operation Temporizing in a half-cured

case of hyperthyroidism always carries with it the danger of the occurrence of thyrotoxic crises

These crises may arise at any time, their cause being unknown, often they are inaugurated by infection, particularly by pneumonia, to which these hyperthyroid patients are apparently particularly susceptible. A sudden increase in the pulse rate occurs, marked excitation, high fever and general collapse. When this stage has been reached, operation is of no avail. It would be foolish to consider radiation. Many times the patient may be brought out of the crisis by means of iodine, but, for the most part, it ends fatally.

SUMMARY

A review of the non-operative treatment of hyperthyroidism is presented—physical, psychic, dietetic treatment and especially the effect of iodine and roentgen-radiation. Their limits and indications are discussed.

THE DIGESTIVE AND ABSORPTIVE FUNCTION OF THE EXTERNAL SECRETION OF THE PANCREAS

By MILTON B. HANDELSMAN, M.D., *Brooklyn, New York*

THERE are some types of investigations which require many years of work before any considerable progress is made, studies of the digestive function of the external secretion of the pancreas are of such a nature. The difficulty in preparing suitable experimental conditions in animals, the care needed in controlling the many variable factors of each experiment, and the lengthy chemical analyses, require in some instances as long as a year to study a single case. J. H. Pratt has since 1907 almost continuously studied some aspect of this branch of physiology, and in recent years has actively directed the work of younger men including Hjort, Falcon-Lesses, Herschenson, Rosenblum, Krakower, Golden, Handelsman, Magendantz and others. The number of publications has been few because of the reasons mentioned, but a vast amount of unpublished data has been collected over the years. Some of these studies will be mentioned here.

In general, studies concerning the effect of excluding pancreatic juice from the intestine have given conflicting results. We have had cycles of beliefs varying from the idea that digestion and absorption of fat and nitrogen may be normal, to the belief that no fat and little protein is utilized in the absence of pancreatic juice. A historical survey shows that these conflicts date from early times.

HISTORICAL

As far back as 1682, Conrad L. Brunner¹ removed a large portion of the pancreas of dogs and claimed that the health and digestion of the animals were unaffected. It was Claude Bernard² in 1856 who showed that shutting off the pancreatic juice by injecting oil into the ducts caused serious disturbances in the absorption of fat.

Practically all the workers after Bernard were unable to confirm his observations. Frerichs³ in 1858 tried to destroy the pancreas by numerous ligatures and fed the animals with fat diets, at postmortem examination the lacteals were found more or less filled with white chyle. Herbst⁴ in 1853 had the same results. Weinmann⁵ in 1853 created pancreatic fistulae in dogs and fed them food rich in fats, he found no fat in the stools. Berard and Colin⁶ extirpated the pancreas in five dogs and left only that

* Received for publication July 20, 1937.

From the Department of Medicine, Long Island College Division of the Kings County Hospital, service of Dr. Tasker Howard.

portion lying next to the portal fissure. The animals lived eight months showing no digestive changes. Bidder and Schmidt ⁷ in Germany also doubted the results of Bernard. Schiff ⁸ in 1862 injected paraffin into the main excretory duct in dogs and found that fat digestion went on normally. Martinotti ⁹ in 1882 asserted that after complete extirpation of the pancreas, no disturbances resulted either in the general condition or in the digestive functions.

The monumental work of von Mering and Minkowski ¹⁰ in 1889 in Naunyn's Clinic which cleared up the relation of the pancreas to sugar metabolism, overshadowed the studies in the same clinic regarding the digestive function of the pancreas which were delegated to Abelman ¹¹ (1890), then a student. Abelman showed that the removal of the pancreas is followed by enormous losses of fat and nitrogen in the stools. When given in the form of meat or lard, almost all the ingested fat was recovered in the stools whereas when the fat was in the form of a natural emulsion, namely as milk, only about one-half was found in the feces. With partial depancreatization, a larger amount was absorbed. De Dominicis ¹² reached the same conclusion. Sandmeyer ¹³ (1895) reported a partially depancreatized dog whose stools showed a greater amount of fat than had been fed.

That the presence of the pancreas in the body was necessary for digestion and absorption was then generally conceded, but that this action was due to the external secretion of the pancreas was denied. Lombroso ¹⁴ (1894) found no disturbance in fat absorption when the pancreatic ducts were tied. Rosenberg ¹⁵ (1898) found that in dogs where the pancreas had been separated from the intestine, there was only slight diminution in the absorption of nitrogen, and the fat absorption after having been normal for two months post-operatively was also very slightly diminished. Zunz and Mayer ¹⁶ (1906) as well saw no digestive changes. Lombroso ¹⁷ (1906) again repeated his earlier work and confirmed his former findings. Burkhardt ¹⁸ (1908) obtained results contrary to the results of the above workers. He found the absorption of foods to be diminished when the external secretion of the pancreas was not allowed to enter the intestine—but when the same dog was allowed to lick the secretion from a pancreatic fistula good absorption occurred. To clear up the dispute, Lombroso ¹⁹ (1908) went to Greifswald where Burkhardt ¹⁸ had done his work, repeated the experiments in the same laboratory in Minkowski's clinic and apparently demonstrated that with the pancreatic juice excluded completely, absorption was good. Fleckseder ²⁰ (1908), Niemann ²¹ (1909) and Brugsch ²² (1909) were also unanimous in their conviction that normal digestion and absorption could take place when the pancreatic ducts were tied and no secretion entered the intestine. This latter view was generally accepted and was incorporated by Adolph Schmidt ²³ (1906) in Von Noorden's "Pathologie des Stoffwechsels."

Many of the above experiments were of dubious value, because the

stools were collected over one day periods which has been shown to be unreliable. However, to explain the above contradictions, three different theories were offered. First Lombroso¹⁹ postulated a pancreatic internal secretion which by its absence did not allow absorption of food when the pancreas was extirpated, but allowed normal absorption even when the pancreatic juice was excluded from the intestinal canal. Secondly, Abelman¹¹ (1890), Rosenberg¹⁵ (1898) and Burkhardt¹⁸ (1908) believed that when the pancreatic ducts were ligated, the digestive ferments enter the blood stream and then are secondarily secreted by other digestive glands, thus entering the intestine by other routes.

The third explanation was that most of the earlier workers had actually failed to exclude the pancreatic juice from the duodenum, and that this accounted for the excellent absorption reported in the absence of pancreatic juice. Hess²⁴ (1907, 1908) after careful anatomical and pathological studies found that there were in many cases three and sometimes four pancreatic ducts in dogs, and that in eight experiments he succeeded only twice in ligating all the ducts. In one of these two instances, only 4.73 per cent of the ingested fat and 54.68 per cent of the nitrogen was absorbed. The other instance showed 48.4 per cent of the fat and 42 per cent of the nitrogen was utilized. This latter result must be accepted with reserve because the dog had double empyema and enteritis. Sinn²⁵ (1907) corroborated Hess' anatomical studies. Pratt, Lamson and Marks²⁶ (1909) further pointed out that even after all the ducts are tied, sinuses may form through the necrotic tissue with the result that pancreatic juice again enters the intestine.

MORE RECENT EXPERIMENTAL EVIDENCE OF THE RÔLE OF THE PANCREATIC EXTERNAL SECRETION IN DIGESTION AND ABSORPTION

It was these investigators, Pratt, Lamson and Marks²⁶ (1909), who first conclusively demonstrated that the confusion of results was due to most of the workers' failure to exclude pancreatic juice from the intestine. Four out of five dogs were successfully operated upon and proved at autopsy to have had all their pancreatic ducts completely ligated so that none of the digestive ferments could have entered the intestine. These animals showed a markedly diminished absorption of fat and nitrogen as evidenced by the enormous quantities found in the stools both by clinical tests and careful chemical analyses. Similar metabolism and absorption experiments on three additional dogs by Francis G. Benedict and Pratt²⁷ (1913) yielded the same results. Vinsentini²⁸ (1914) brought forth more experimental evidence in five dogs with completely ligated ducts also showing that there was a marked decrease in fat utilization. Brugsch²⁹ (1919) published a report of work done from 1912 to 1915. He was able to ligate the pancreatic ducts and to exclude completely the pancreatic juice in only three out of eight attempts. Those animals successfully operated upon showed a marked diminution of nitrogen and fat absorption leading Brugsch to change his former views and to agree with Pratt.

It must be pointed out in this connection that despite the above experimental results Lombroso³⁰ (1931) again reaffirmed his beliefs that an internal secretion of the pancreas controls fat absorption. Umber³¹ (1926) and Lesser³² (1925) writing in recent German "Handbucher" still put considerable credence in Lombroso's theory. However, McClure, Vincent and Pratt³³ (1917) showed by direct experimentation that "the absorption of food was no less when the pancreas of a dog was entirely removed from the body than when the pancreas was left in the body but its secretion excluded from the intestines." Vinsentini²⁸ (1914) obtained only slightly better absorption of fats in dogs with the pancreatic ducts ligated than in those from which the pancreas had been removed. Licht and Wagner³⁴ (1927) and Falcon-Lesses and Herschenson³⁵ (1931) conclusively demonstrated that the absorption of foods was the same in dogs in which first only the pancreatic secretion was blocked and then later the pancreatic remainder removed. These studies would tend to discredit completely Lombroso's theory of an internal secretion.

TABLE I

Results obtained by various workers regarding the percentage of dietary nitrogen and fat absorbed in dogs when the external secretion of the pancreas was unquestionably excluded from the intestines

| Author | % Nitrogen Absorbed | % Fat Absorbed |
|--|---------------------|----------------|
| Pratt (1907)—ducts ligated | 22.2-61.7 | 4.8-76.6 |
| Vinsentini (1914)—ducts ligated | — | 28.7-44.0 |
| Vinsentini (1914)—after pancreatectomy | — | 8.7-25.7 |
| Cruikshank (1915)—one stage pancreatectomy | 78 | 32.6 |
| Cruikshank (1915)—two stage pancreatectomy | 79.6 | 72.12 |
| Brugsch (1919)—ducts ligated | 21.8-33.5 | 0-21.8 |
| Licht and Wagner (1927)—ducts ligated and after pancreatectomy | 55 | 0 |
| Pratt, Falcon-Lesses and Herschenson (1931)—ducts ligated | 85.3 | 93.6 |
| Pratt, Falcon-Lesses and Herschenson after pancreatectomy | 56.2 | 95.2 |
| Pratt (1934) with Handelsman and Golden—ducts ligated | 47-60 | 41.5-93.7 |
| Selle (1937)—after pancreatectomy | — | average 89.51 |
| Greenberg (1933) in cats—ducts ligated | 51.2-66.8 | 0-28 |

Greenberg (1933)⁹¹ employing cats obtained results similar to those of Brugsch and Licht and Wagner. He also obtained more fat excreted in the stools than fed.

Although it is now agreed by most experimenters that the exclusion of the external secretion of the pancreas interferes with the digestion and absorption of fats and proteins, there still is tremendous difference of opinion as to how great a rôle it is that the pancreas actually plays. Particularly regarding fat absorption has there been great disagreement, some workers reporting no absorption and others obtaining normal values. We have tabulated the results obtained by various workers in table 1.

It can be seen that Brugsch²⁹ (1919) and Licht and Wagner³⁴ (1927) report no fat at all absorbed while Falcon-Lesses and Herschenson³⁵ (1931)

obtained almost normal absorption. It must be pointed out, however, that Licht and Wagner give no experimental data and a perusal of Brugsch's report reveals that he did not analyze his diets but based his calculations on the amount of solid fat added to the food. If the lipid content of the meat fed were also taken into account, the percentage of fat absorption in Brugsch's animals would probably be greater.

Cruikshank³⁶ (1915) first pointed out the importance of the general well being of the animal when absorptive studies are made. Working in Starling's laboratory he showed that a dog which had been carefully depancreatized in a two stage operation absorbed a large percentage of fat, whereas a dog which had been completely depancreatized in one operation absorbed a much smaller amount. Pratt with Falcon-Lesses and Herschenson³⁵ (1931), giving particular attention to the dogs—a carefully regulated diet which was given in frequent small feedings and included vitamins, as well as plenty of sunshine, exercise, etc.—found that practically normal absorption took place at times in both depancreatized dogs and animals with their ducts ligated without the addition of pancreas in the diet. These animals, however, showed a labile digestive ability and at other times passed the typical large, bulky "pancreatic" stool.

In a further attempt to analyze this situation Pratt directed Handelsman and Golden³⁷ (1934) to study three dogs with their pancreatic ducts ligated to observe the effect of varying the food components and of varying the quantity of food ingested on the absorptive ability of the animals. No definite relation to the type of food ingested was found. Large quantities of food when given were absorbed in the absolute sense but showed a relatively greater amount excreted in the feces. Furthermore, the animals could not tolerate very large diets for longer than two weeks before an enteritis occurred which responded to treatment when smaller diets were given. They were led to conclude that factors which are as yet unknown influence absorption since not only did the same dog respond differently to the same diet, but different dogs under the same experimental conditions responded in an irregular fashion. The exact role of the vitamins added to the diet, a factor neglected by the earlier workers, is not known. Nasset, Pierce and Murlin³⁸ (1931) showed that there is no effect of yeast on the amount of nitrogen excreted through the feces in depancreatized dogs. The work of Mottram, Cramer and Diew³⁹ (1922) showing by histological studies that vitamins hasten fat absorption, has not as yet been studied in animals without pancreatic juice. However, both Pratt and Ivy⁴⁰ have been impressed with the marked importance of vitamins in their experiments particularly in maintaining the animals in good health and with good fat absorption.

THE LENGTH OF LIFE OF ANIMALS WITHOUT EXTERNAL PANCREATIC SECRETION

Experimenters working with depancreatized dogs reported that these animals died of inanition although they ate large amounts of food and their glycosuria was controlled by insulin. This group of workers did not chemically analyze the stools and reported "tremendous amounts" of fat in the stools microscopically. Since quite early it was found that life could be prolonged in these animals by including raw pancreas in the diet, it was assumed that enzymatic action was the beneficial factor. In 1924 Fischer⁴¹ and Allen, Bowie, McLeod and Robinson⁴² pointed out the importance of fatty infiltration of the liver in these animals as a cause of death. Further studies by Hershey and Soskin⁴³ (1932) and Best⁴⁴ (1934) and his co-workers have revealed that lecithin and choline as well as the feeding of raw pancreas can prevent this. The literature on this subject has recently been reviewed by Greene, Handelsman and Babey⁴⁵ (1937).

Berg and Zucker⁴⁶ reported fatty infiltration of the liver following pancreatic fistulae. A perusal of many autopsy records of dogs with ligated pancreatic ducts studied by J. H. Pratt (unpublished) reveals no case with evidence of abnormal infiltration of the liver with fat. This coincides with the experience of Von Prohaska, Dragstedt and Harms⁴⁷ (1936) who also find no relationship between the deprivation of the external secretion of the pancreas and fatty livers. Bloom and Handelsman⁴⁸ reported a case of a young dog with naturally occurring diabetes which died because of fatty changes in the liver (jaundice, etc.). The acinar tissue was for the most part well preserved and stool studies revealed no evidences of pancreatic secretion deficiency, but practically no islets of Langerhans were found. An internal secretion of the pancreas which prevents the occurrence of fatty livers has actually been isolated by Dragstedt, Von Prohaska and Harms⁴⁹.

Absence of the external secretion of the pancreas from the intestine does not seem incompatible with a fairly long and healthy life. Several of J. H. Pratt's dogs with ligated ducts lived for long periods of time. "Zep" lived for over three years and "Nellie" over 2½ years without ever being fed pancreas or enzymatic preparations.

Complete pancreatic fistulae with continuous loss of the secretion outside the body leads to death in five to eight days. The mechanism leading to the fatal ending in these cases has been studied by Elman and McCaughan⁵⁰ and others,⁵¹ and has been found not to be related to the digestive function of the pancreatic secretion but to the acid-base economy of the animal. Large quantities of physiological saline administered to such dogs can prolong their lives for a longer period of time.

THE DIGESTION AND ABSORPTION OF FATS IN THE ABSENCE OF PANCREATIC JUICE

The pancreas played the rôle of "star witness" in the earlier arguments of the physiologists as regards the necessity of the splitting of fats before

absorption. However, fat recovered in the stools is for the most part well split even when the greatest source of lipase, the pancreatic juice, is absent from the intestine. This fact was first noted in the first animal experiments of Abelman¹¹ in 1890 where depancreatized dogs were used. Pratt, Lamson and Marks²⁶ (1909) also found excellent hydrolysis of the fats in the stools of animals whose pancreases were allowed to remain in the body with the pancreatic ducts blocked, for example, one of the dogs studied excreted 88.7 per cent of the ingested fat in his stools and 70 per cent was in the form of fatty acids and soaps. H. Wendt⁵² in his review has collected the clinical literature on this subject with the same conclusions.

The factors involved in the mechanism of this excellent fat splitting in the absence of pancreatic juice have been puzzling. Three other sources of lipolytic activity have been known to exist. Volhard⁵³ clearly established the presence of a fat hydrolyzing enzyme in the stomach which is active in acid medium, and Boldyreff⁵⁴ (1905) demonstrated an enzyme of similar nature in the intestine. It has been known that many bacteria also have the power to split fats particularly in the colon.

Umber and Brugsch⁵⁵ (1906) interested themselves in this problem first suggested that the gastric lipase might play a rôle when there was a deficiency or absence of pancreatic juice. They reported a single observation on sacrificing a depancreatized dog, the fat collected between the pylorus and papilla was only 18.2 per cent split whereas that in the lower ileum was 42 per cent split. This made them minimize the importance of the gastric lipase and led to search for lipase in other organs.

Gross⁵⁶ (1912) in studying two cases where atrophy of the pancreas was clinically diagnosed (one case later proved at autopsy) searched for a cause of the excellent splitting of fats in these cases. He found in these patients that gastric juice when left with neutral fat in an incubator at 38° for an indefinite length of time split the fats. Since this did not occur when toluol or chloroform was added, he supposed that bacterial action in the stomach and upper intestine caused these results.

Nothmann and Wendt⁵⁷ in 1931 criticizing Gross' results instituted experiments on five depancreatized dogs to which they fed olive oil test diets. The dogs were killed from four to eleven hours after having been given the test diets and the fats in the small intestine were analyzed quantitatively and for the amounts hydrolyzed. They found only 2.01 per cent to 3.98 per cent of the fats in the small intestine split whereas in the large bowel 14.82 to 22.11 per cent were in the form of fatty acids and soaps. This led them to emphasize the lipolytic activity of the bacteria in the colon. In two of their experiments wherein the total fats remaining in the intestinal canal were determined, they were able to recover 89 per cent of the ingested fat in one case and almost 100 per cent in the other. The amount of fat absorbed as well as the poor splitting stands in contrast to the experiments where excellent absorption of fats has been found when balanced diets are

fed to the animals We have tabulated from reports in the literature the results of analyses of intestinal contents of dogs killed after a normal meal and have included some unpublished results obtained by J H Pratt (table 2)

TABLE II

| % Split in | Normal Dogs | | | Depancreatized Dogs | | Dogs with Pancreatic Ducts Ligated |
|--------------------|------------------------|----------|-------------------|---------------------|-----------------|---|
| | Starling and Pincussen | Abelmann | Umber and Brugsch | Umber and Brugsch | Pratt (unpubl) | "Toby" Pratt, Golden and Handelsman (unpubl) |
| Stomach | 30-40% | — | — | — | — | 31 3% |
| Duodenum | — | — | 30 2% | 18 2% | — | 32 3% |
| Jejunum | — | 32% | — | — | 41 5% | — |
| Ileum | — | 57% | 48 9% | 42 0% | 46 4% | 31 9% |
| Colon | — | 76% | 81 0% | 72 9% | — | 45 0% |
| Stools (same diet) | — | — | — | — | — | 51-55% |

A careful analysis of the factors that contribute to these opposite results obtained with olive oil administration in contrast to balanced diets revealed interesting results Nothmann and Wendt ⁵⁸ found that after iodipin and egg yolk mixtures, roentgen-ray studies in depancreatized dogs showed enormously rapid gastric emptying time They checked this observation with quantitative chemical analyses of the gastrointestinal contents of depancreatized dogs killed at various intervals after being fed olive oil test meals Independently, Beguria working in the Tufts College Physiology Laboratory with olive oil-barium sulfate mixtures obtained similar results in roentgen-ray studies of depancreatized dogs, in some dogs, the olive oil mixture was in the ileum in one hour with complete emptying of the stomach by that time

Unpublished roentgen-ray studies by Pratt done in 1917 revealed only very slight changes in the gastrointestinal motility of several depancreatized dogs and animals with their pancreatic ducts tied These studies were done with plain barium sulfate suspensions or with ordinary canine diets mixed with barium This was substantiated by other methods In practically none of our dogs did carmine appear in the stools before 15 hours, usually 24 hours Furthermore on sacrificing one dog four hours after a meal 58 per cent of the food was still in the stomach and only 11 per cent was in the proximal colon Yesko ⁵⁹ and Fauley and Ivy ⁶⁰ found a slightly decreased gastric emptying time in such dogs, the latter attribute this as due to a normal hunger mechanism

Dr Beguria was kind enough to do gastrointestinal series on two of our dogs with ligated pancreatic ducts With ordinary barium sulfate suspension in water, a practically normal motility was found, but with the olive

oil-barium sulfate mixture, an extremely rapid gastrointestinal motility was demonstrated. This latter result stands in contrast with the work of Nothmann and Wendt⁵⁸ who did not find the rapid passage of the olive oil in dogs with ligated pancreatic ducts but only in depancreatized dogs. Because of their findings, they proposed the theory that an internal secretion of the pancreas regulates gastrointestinal motility. The studies of Pratt and Beguria do not offer warrant for such a theory.

The unusual acceleration of the passage of olive oil and iodipin through the intestines, a condition which does not occur with usual diets in the absence of pancreatic juice, explains the extreme differences in digestion and absorption found by Nothmann and Wendt⁵⁷ and other workers. This specific "diarrhea" of the oils does not allow sufficient time for their splitting and absorption. This difficulty does not exist with other foods.

The problem of how the fats of usual diets are split in the absence of pancreatic lipase cannot be explained entirely by slow intestinal motility. A perusal of table 2 reveals that a considerable amount of fat is already split in the stomach (25 to 30 per cent) in both normal and depancreatized dogs. Careful control studies by Pratt and Golden (unpublished) revealed that the diets of dogs in the Tufts laboratory were in some instances already 10 to 15 per cent split before ingestion. This was traced to the use of cans of Klum opened for a time before use. In other unpublished experiments, the gastric contents of two dogs with ligated pancreatic ducts were analyzed four hours after feeding and yielded 23.5 per cent to 27.2 per cent of the fats in the split form. Although this is minimal when compared to the 40 to 50 per cent splitting usually found in the ileum, the gastric lipase may really be of some significance. Pratt, Golden and Handelsman (unpublished) studied the pH of the intestinal contents of dogs without pancreatic juice who were killed four hours after a meal. The hydrogen-ion concentration showed strong acidity throughout. The studies of Hoerner⁶² showed that normally the pH of the duodenal content may range from 7.81 to as low as 3.31. In dogs without pancreatic secretion, although the range found was within these limits, the lower hydrogen-ion values were most often found. Since the gastric lipase hydrolyzes fats optimally in an acid medium, its action may possibly be carried on in the lower intestinal canal in the absence of pancreatic juice.

Minkowski⁶³ (1890) expressed the belief that an intestinal lipase hydrolyzes the fat. However, the importance of intestinal lipase is minimized by Hull and Keeton⁶⁴ who find the concentration of gastric lipase five times greater. Also Koskowski and Ivy⁶⁵ (1926) found no change in the *succus entericus* in the absence of pancreatic juice and Fauley and Ivy⁶⁶ found a hypersecretion of gastric juice under those conditions.

The other locus of lipolytic activity, the colon, does not seem to be important regarding fat absorption. Nakashima⁶⁶ (1914) and Verzár⁶⁷ (1937) have found no evidence of the ability of the colon to absorb fat although Yamakawa⁶⁸ (1929) claims this to be possible.

Studies of fat absorption approached from other angles have clarified the rôle that fat splitting actually plays in the resorption of fat. Pflüger⁶⁹ (1901) had advanced the "saponification theory of absorption" and insisted that there must be complete splitting of fats before absorption could take place. On the other hand Mellanby⁷⁰ (1928), minimizing the importance of fat hydrolysis, showed that the amount of lipase in the pancreatic juice of a cat is so small that it could merely serve as a mechanism to initiate emulsification of the ingested fat by providing only a very small amount of soap. F. Verzar (1936) has reviewed the literature on this subject as well as his own works which have clearly demonstrated the importance of lipase and bile in fat absorption. He showed that neither fine emulsions of a neutral fat, nor neutral fat together with lipase, nor neutral fat emulsified with bile acids were absorbed from the intestines of dogs whose bile ducts were tied. But when neutral fats were put into the intestines along with lipase and bile acids, 74 per cent were absorbed after 24 hours. The bile acids do not act upon neutral fats, but they form physical complexes with fatty acids resulting in combinations which are more soluble and diffusible than either of the parent components and which are easily absorbed. These results have been confirmed by Riegel, Elsom and Ravdin.⁷¹

From these studies it can be seen why good fat absorption may take place in the absence of pancreatic juice as long as some lipolytic agent initiates the hydrolysis of neutral fats. The finding that an animal without pancreatic secretion entering the intestines may show good absorption at one time and poor at another time indicates that other factors as yet unknown must play a great rôle. Further studies must clarify the importance of vitamins, mineral content, the differences of various fats, etc.

Since the fatty acid-bile acid complexes described by Verzar⁶⁷ are broken down in a medium with a pH below 6, and since the pH of the intestinal canal of a dog without pancreatic juice can be as low as 3.5, another factor suggests itself for study. One would suspect that the administration of alkalis might aid fat absorption, but experiments by Poczka and Fischel⁷² on a patient with pancreatic insufficiency showed that such treatment actually increased fat excretion.

Experimental studies involving the administration of pancreas (fresh or extracts) to animals without pancreatic secretion have been contradictory and give no conclusive proof of the rôle played by pancreatic lipase. The consistent improvement obtained in the digestion of proteins and carbohydrates in such substitution experiments does not seem to hold for fat. Pratt, Lamson and Marks²⁶ believed they obtained better fat absorption after the administration of pancreatic extract. Nothmann⁸⁰ found marked improvement in fat absorption in depancreatized dogs when large doses of "pankrophorin" were given. Absorption studies in a patient with achylia pancreatica by Poczka and Fischel⁷² revealed that the majority of proprietary preparations in Germany with the exception of "Pancreatol-dispert," did not

prevent fat loss in the stools. Very recent experiments with depancreatized dogs by Selle⁸¹ using enteric coated as well as plain pancreatic extracts (potent in vitro) showed no improvement in fat absorption, although in the same experiments the nitrogen utilization was markedly increased. However, Selle who reported no benefit, had excellent (90 per cent) fat absorption even without the administration of pancreatic enzymes whereas Nothmann and Wendt who were impressed with the efficacy of oral pancreatin in depancreatized dogs had had previously only 43 per cent of the dietary fat absorbed. Similarly Sarzana⁸² who obtained only 50 per cent absorption of olive oil in pigeons with ligated pancreatic ducts, also noted improvement up to 84 per cent absorption when pancreatic juice was given along with the fat. These differences in reports of success in pancreas administration point again to the numerous complicating factors controlling fat absorption.

THE NATURE OF THE FAT IN THE FECES OF ANIMALS WITH PANCREATIC STEATORRHEA

Bloom, Sperry and their co-workers⁷³ have shown the lack of relationship between dietary fat and the fat excreted in the stools of normal animals. A Krakower⁷⁴ has shown this to occur also in humans. In normals, after all the dietary fats are absorbed, apparently fat is again excreted by the intestines to form the fecal lipoids which are entirely independent of the food ingested.

Studies in Pratt's laboratory by Krakower and Rosenblum (unpublished) revealed a close similarity of the fat in the stools of animals deprived of pancreatic juice to the dietary fat. When fed olive oil, the iodine number of the fecal fat approached that of olive oil, when butter was fed, the iodine number of the fecal fat approached that of butter.

The external pancreatic juice has been found by Tangl and Berend⁷⁵ (1930) and Tangl⁷⁶ (1932) to contain a "dehydrogenase" which is activated by bile. Berend⁷⁷ (1933) demonstrated such an active enzyme in the pancreas alone and Quagliariello⁷⁸ isolated a desaturating enzyme in bile alone. Artom⁷⁹ has reviewed experiments by Italian workers demonstrating similar desaturation of fats by many tissues and even by *B. coli*. On the other hand, there is evidence that unsaturated fats may be preferentially absorbed. Apparently these factors did not influence the fats studied by Krakower and Rosenblum in the above experiments with dogs whose ducts were ligated. In other experiments where Nucoa was employed instead of butter or olive oil, the close similarity between ingested and excreted fats was not obtained, the latter being more unsaturated. It is possible that this difference was due to the presence of desaturating enzymes in the intestinal canal.

THE DIGESTION AND ABSORPTION OF CARBOHYDRATES IN THE ABSENCE OF PANCREATIC JUICE

Clinically it was maintained by F. Mueller that the digestion of starches was not necessarily impaired in the absence of pancreatic secretion. Furthermore, studies on "intestinal catarrh" and cases with increased gastrointestinal motility due to causes other than pancreatic disease have shown large amounts of carbohydrates in the stools. Thus the presence of starch in the stools has been more or less neglected by the clinicians as a comparatively insignificant factor in the absence of pancreatic enzymes in the intestine.

Rosenberg¹⁵ in 1896 pointed out the presence of starch in the stools in these cases. It is only recently that this problem has been studied experimentally. Dogs lend themselves well to this study since their saliva contains no ptyalin. Hjort³⁵ working in Pratt's laboratory studied normal dogs on a comparatively large diet of ground meat, cracker meal, butter and vitamins and found the stools to contain only 1.08 per cent starch (analyzed as sugar), the same animal after the pancreas had been completely separated from the intestine passed stools containing 14.23 per cent starch (as sugar). Handelsman, Golden and Pratt (unpublished data) found the stools of two dogs with similar operative interference to consist of 0 per cent to 9.1 per cent carbohydrate (analyzed as sugar) when diets low in carbohydrates were fed, and to contain 21.5 per cent to 46.6 per cent sugar when high carbohydrate diets were fed. Beazell, Schmidt and Ivy⁸³ fed dogs with the pancreas separated from the intestine with diets containing 62 per cent starch, and they found that 18 per cent to 39 per cent of the stools consisted of starch. Sekikawa⁸⁴ found that feces of normal animals contain 80 to 190 mg carbohydrate per gram of stool, after ligation of the pancreatic ducts the carbohydrate concentration of the stools rose to 190 to 230 mg per gram of stool while after pancreatic fistula the concentration was still higher, 240 to 500 mg per gram of stool.

Studies of the percentage of starches in the stools do not give a true picture of the amount actually absorbed. A good example of this occurred in the dog "Nellie" where Pratt and his co-workers found after a high carbohydrate meal absorption of 92.6 per cent of the ingested cracker meal, yet stool analysis showed 30.1 per cent of the feces to consist of carbohydrate. For the most part, carbohydrates seem to be more than 90 per cent absorbed, when the intake is not too excessive even in the absence of pancreatic juice and this good absorption seems to be independent of the relative fat and protein content of the diet.

To explain this good absorption, recently Zucker, Newburger and Berg⁸⁵ (1932) again renewed the theory of Rosenberg¹⁵ that the pancreatic enzymes may be secreted by other organs. These workers studied the increased serum and urinary amylase in dogs whose pancreatic ducts were blocked and were impressed with the fact that the disappearance of the in-

creased serum amylase is not accounted for by its excretion in the urine. They report evidence of increased amylolytic activity of the bile in cases where the pancreatic ducts have been tied. This was first demonstrated in birds by Langendorff⁸⁶ in 1879. This type of compensatory mechanism was also studied by Schegalow⁸⁷ in 1902 who reported increased proteolytic activity in the bile after ligating the pancreatic ducts and Lombroso¹⁷ (1906) who found the same for lipase. Pfluger⁸⁹ (1905) expressed his approval of this theory. However, the excellent absorption of carbohydrates reported by Pratt³⁵ in dogs with the pancreas removed from the body does not allow much importance to be attached to this theory.

Beazell, Schmidt and Ivy⁸³ found that administration of pancreatin as well as other diastase preparations markedly decreased the amount of carbohydrate in the stool of dogs with their pancreas completely disconnected from the intestine. Such excellent therapeutic results would tend to substantiate the impression that it is actually the absence of diastatic digestion in depancreatized dogs that leads to the excretion of carbohydrates in the stools rather than other causes such as rapid gastrointestinal motility, improper pH of the intestine or interference with the absorptive processes.

That the compensatory mechanism of carbohydrate digestion can be strained in some cases by the excessive administration of starchy foods was shown by one of Pratt's dogs³⁵. This animal was unsuccessfully operated upon and not all the pancreatic ducts were ligated as was proved at autopsy and also noted clinically by the absence of the typical "pancreatic stools". Whereas fat and nitrogen were normally absorbed, large quantities of starch appeared in the stools. Apparently in this case of hypochylia pancreatica, the amount of pancreatic juice was insufficient for the complete digestion of carbohydrates.

THE DIGESTION AND ABSORPTION OF NITROGENOUS FOODS IN THE ABSENCE OF PANCREATIC JUICE

In normal animals, the amount of fecal nitrogen does not vary with changes in the amount of ingested nitrogen, and even remains the same on a protein-free diet. The fecal nitrogen may be increased by raising the indigestible, non-nitrogenous bulk of the diet while changes in the digestible food components have practically no effect⁹⁰. It would seem that the fecal nitrogen originates in a manner similar to that of fecal fat, namely as a secretion product of the bowel rather than being a true indigestible residue.

In dogs without pancreatic juice entering in the intestine, usually 35 per cent to 55 per cent of the ingested nitrogen is excreted in the stools. Similar results have been obtained in cats by Greenberg⁹¹ who found 33.2 per cent to 48.8 per cent excreted. Occasionally higher values are obtained (see table 2). That this increased fecal nitrogen represents the undigested food nitrogen has been recognized by clinicians by tests with cell nuclei and striated meat fibers found in the stools after the ingestion of meat. Detailed

chemical studies of the type of nitrogen found in the stool of depancreatized animals have not been made probably because of the difficulty in controlling gastrointestinal motility as well as bacterial putrefaction in the colon (Review by Pratt ⁹²) There is also a lack of data concerning the intermediary protein breakdown products in the intestine in the absence of tryptic digestion, a phase in which the gastrointestinal allergists are now interested

F G Benedict and Pratt ²⁷ studied the specific dynamic action of meat feeding in dogs in which the pancreatic secretion was absent After the feeding of 500 grams of meat, the 24 hour increment in CO₂ production was 28 per cent for a normal animal, compared to 17 per cent and 22 per cent in experimental animals, after 750 grams of meat the increase in metabolism in a normal dog was 62 per cent as compared with 48 per cent, 43 per cent and 25 per cent in animals without pancreatic secretion Kúthy ⁸⁸ by direct experimentation in normal rats has established that the specific dynamic action of proteins parallels their absorption rate The data of Benedict and Pratt on closer examination reveal that the increased CO₂ production of the experimental animals after meat feeding as determined over four hour periods, approximately parallels that of the control animal with the exception that there was a diminution in the quantity produced Since the animals were in nitrogen balance, it would seem that protein absorption in animals without pancreatic juice proceeds normally except for the decreased amount of absorption

The problem of nitrogen balance in depancreatized dogs has been studied by Nasset, Pierce and Murlin ³⁸ who showed that such dogs may have an increased nitrogen retention or normal balance even when large quantities of nitrogen are lost in the stools

An interesting problem has been brought up by the work of Selle ⁸¹ who found that pancreatin administration reduced the weight of the stools of depancreatized dogs by 50 per cent and reduced the fecal nitrogen 35 per cent to 65 per cent Fat excretion in these animals, 10 per cent to 11.4 per cent, was almost normal, and was uninfluenced by pancreatin administration Since no carbohydrates were fed to these animals during the metabolism periods, it would seem that the reduced bulk of the stools after pancreatin paralleled the decreased nitrogen excretion This observation is interesting inasmuch as the bulkiness of the pancreatic stool is one of its typical features A perusal of the fecal analyses by Handelsman, Golden and Pratt ³⁷ reveals a relationship between increased nitrogen ingestion and the increased dried weight of the stools, but the bulkiness did not seem to depend upon an increase in the percentage of nitrogen in the stool or on the percentage of nitrogen absorbed The enormity of the "pancreatic stools" has not been completely explained Incomplete studies in Pratt's laboratory with the diets used would seem to indicate that the dried ash content of the stools is not the cause of the large size of the feces On calculating the results of many careful dried stool analyses there has been found an "un-

determined residue" when the carbohydrates, fat, ash and proteins ($N \times 6.25$) have been totaled. This undetermined residue is probably greater than calculated since a part of the nitrogen in the stool is not from protein.

CONCLUSIONS

Care must be used when studying the literature concerning the external secretion of the pancreas. The earlier studies reported good absorption of food when the pancreas was separated from the intestine and attributed this to an internal secretion of the pancreas regulating absorption. However, these conclusions were based on experiments where the pancreatic juice was not completely excluded from the intestine. After more careful surgical interference the same digestive disturbances were found as after pancreatectomy. Although the early experiments showed rather poor absorption of foods, in later studies employing smaller feedings, including vitamins, and giving more care to the general well-being of the animal, fairly good absorption of foods occurred. In contradiction to the good absorption of the unsuccessfully operated dogs, the animals actually without pancreatic secretion in the intestine show a labile digestive mechanism good at times and poor at other times. Only in the carbohydrate fraction does this lability seem to depend on the diet as manifested by a higher percentage of carbohydrate in the stools. The nitrogen and fat absorption are also labile, but the factors causing these variations are not completely understood. Fat digestion and absorption are particularly complicated. The duty of the pancreatic juice seems to be to split the neutral fats in preparation for the absorption of the fatty acids combined with bile acids. In the absence of the pancreas a compensatory mechanism splits the fats, the gastric lipase may play some rôle in this. The significance of the lowered pH of the intestinal canal in the absence of pancreatic juice as well as a singularly rapid gastrointestinal motility when oils are fed is not as yet known. Most of the digestive and absorptive phenomena found in depancreatized dogs are found in dogs with their pancreatic ducts ligated. The internal secretions postulated to explain fat absorption or to regulate gastrointestinal motility are not substantiated. The fatty infiltration of the liver in depancreatized dogs, however, seems to be related to an internal secretion of the pancreas.

CASE REPORT

THE SYNDROME OF DYSPHAGIA AND ANEMIA

By LEMUEL C. MCGEE, Ph D, M D, and T. MARTIN GOODWIN, M D,
Elkins, West Virginia

"THERE is a variety of dysphagia, not uncommon in middle-aged women, which in all cases presents almost identical signs and symptoms and which reacts uniformly to treatment, but as to the pathology of which we are ignorant." This statement by Brown Kelly¹ in his original discussion of the subject is still true of the syndrome he described. Kelly¹ and Paterson,^{2,3} in 1919, outlined the symptom complex of "spasmodic dysphagia" as one clearly distinct from that of "globus hystericus," achalasia of the cardia or organic obstructive lesions of the esophagus. Their patients were women, the majority of whom were between 40 and 50 years of age. The outstanding symptom in each patient was either a slowly or a rapidly appearing dysphagia, referred to the level of the larynx, in the absence of any previous chemical or thermal esophageal injury. Several patients related symptoms common to the neuroses. Most of them were undernourished. Both authors found a pallor of the pharyngeal mucous membrane, the tongue surface smooth and devoid of papillae. The mouth corners were fissured, there was notable pyalism. In several patients an easily ruptured membrane extended transversely across the entrance to the esophagus. In others there were firm, approximated bands in the mucosa forming a closure of the gullet at the site of the complaint. These bands apparently were not on a cicatricial base and yielded readily to pressure from a tube, bougie, or endoscopic instrument. In many instances there seemed to be simply increased muscular tone at the entrance into the esophagus. The patients had no intermittent symptoms or other characters of hysteria. Dilatation maneuvers gave the patients definite relief and Kelly concluded, from a particular study of 10 patients, that the disorder was a spasm of esophageal muscle developing as a result of faulty innervation, probably failure of a proper local reflex arc through the plexuses of Auerbach and Meissner.

Vinson,⁴ in association with Plummer, after observations on 69 patients (only 12 were males) was impressed with the occurrence of an anemia of the hypochromic type in dysphagia. The onset of the disease in the majority of his patients was marked by a rather sudden hindrance in swallowing solid food. The symptoms often were tolerated for years before a physician was sought. Roentgenographic and esophagoscopy examination gave no evidence of disease. Twelve of these patients had palpable spleens. The passage of an esophageal sound gave excellent results when followed by Bland's pills, Fowler's solution and encouragement to eat. Vinson was impressed also by the hysterical manifestations of these patients. Since this report in 1922, the disorder frequently

* Received for publication April 22, 1937. From the Golden Clinic, Davis Memorial Hospital, Elkins, West Va.

has been called the Plummer-Vinson syndrome. Moersch and Connor⁵ collected a series of 65 such hysterical dysphagias, all being found in women between the ages of 23 and 63 years.

Hurst⁶ reported a case which suggested that infection of the throat, as by streptococci, might give rise to a reflex spasm in the esophagus. Ryle⁷ reported a patient having no delay in the passage of barium and in whom he felt hysteria was the etiologic factor. Cameron^{8, 15} reported an analysis of 25 case studies. He emphasized the smooth, pale, dry mucous membrane of the mouth and fissures extending from the mouth corners over the skin. All of his patients were women between 41 and 60 years of age. The dysphagia usually was located at the level of the larynx. Splenomegaly was found in eight instances. In 15 patients, the hindrance in deglutition appeared to have preceded the anemia. Cameron considered atrophy of the mucous membrane, with the probable loss thereby of both mucous secreting glands and properly functioning sensory nerve endings, as of great significance in the mechanism of the dysphagia. Jones and Owen,⁹ in summarizing the clinical characters of the disorder, were impressed by the long duration (one to eight years, in their experience) of the dysphagia. Evans,¹⁰ considering the disorder not a local disease but a local manifestation of a general disease, presented incomplete evidence that syphilis may have been the causative factor in some instances. He referred to a necropsy on one patient but gave no details as to the microscopic findings in the esophagus. Witts¹¹ described anemia and dysphagia in 13 women with characteristic findings and excellent response to therapy with iron. The anemia was definitely microcytic in all but one patient.

Suzman,¹² in 1933, reviewed the previously reported cases and added eight from his experience. One of his patients died following perforation of the esophagus by an unguided filiform bougie. In an autopsy on this patient, the sections from the esophagus showed marked desquamation of the superficial epithelium and a few areas of unequivocal keratinization. There was moderate infiltration by lymphocytes and plasma cells. The musculature was atrophied. Of greatest importance was his observation that there were no demonstrable changes in the nerve plexuses. Hoover¹³ reported on a series of 17 cases, in seven of which a definite band or web was found in the upper end of the esophagus. He observed that the passage of the esophagoscope alone relieved the dysphagia in most instances. McGibbon,¹⁴ from a study of seven such patients, emphasized a characteristic glossitis, stomatitis and atrophic pharyngitis as the essential findings. Splenomegaly, koilonychia, achlorhydria, fissures at the angles of the mouth, brownish discoloration of the skin and increased fragility of the erythrocytes were occasionally associated with the syndrome. Five of his patients had a web or other demonstrable upper esophageal lesion.

Many of the reported histories indicate that dysphagia precedes the onset of anemia but occasionally the reverse is true.¹⁵ Patterson³ stated that the anemia comes late in the disease and is to be regarded as a secondary manifestation of the dysphagia. Benhamou and Cohen-Solal¹⁶ regarded the entire symptom complex as being secondary to an essential hypochromic anemia.

Proper consideration of dysphagia resulting from a failure of the introitus of the esophagus to receive and adequately transmit solid food and fluids, requires a careful elimination of palpable lesions which may give similar symptomatology. Such recognized causes of obstruction are retropharyngeal ab-

sciss, bulbar paralysis, pharyngeal, laryngeal or esophageal neoplasm, congenital malformation, foreign body, cicatricial contraction, pulsion or traction pouch, mediastinal mass, and others carefully listed by Hutchison¹⁷ Impaired deglutition has been noted in patients with scleroderma, progressive muscular dystrophy,¹⁸ exostoses of margins of cervical vertebrae,¹⁹ and unilateral pulmonary fibrosis²⁰

Since the treatment of this well identified clinical syndrome has been remarkably successful, rarely does an opportunity for postmortem study appear There have been found but two previously reported autopsies on patients who had the clinical syndrome of idiopathic dysphagia and anemia^{10, 12} The patient in the following case report had no demonstrable cause for dysphagia The pressure of the thyroid lobes on the esophagus was associated with normal deglutition for too long a time for it to serve as an explanation of dysphagia The age of the patient when her symptoms appeared and the manner of her death, exsanguination by bleeding from multiple points in the gastrointestinal tract, are unusual

CASE REPORT

Mrs E H, aged 66 years, entered the Davis Memorial Hospital, January 17, 1936, complaining of loss of weight and weakness for the previous six months and of dysphagia for six weeks The embarrassment in deglutition was slight until January 14 For the few weeks prior to the latter date she observed that both liquid and solid foods were swallowed with some difficulty Three days before admission her son observed that she seemed to be unable to take any of her food and that saliva drooled from her lips as she attempted to swallow She left the table in the middle of the meal and took little or no nourishment during the next two days She complained of no fatigue in mastication There was a known loss of 30 pounds in weight in the six months prior to her hospital admission

The patient had been in apparent good health previously, save for a few aching pains, of the type associated with hypertrophic arthritis, in the lower back and thighs since the age of 60 years The menses ceased at the age of 40 years Her mother died at the age of 58 years with a clinical diagnosis of carcinoma of the stomach

The patient was cachectic, weighing but 81 pounds, and could scarcely walk from weakness Her skin was generally atrophic and loosely attached to the body Several fissure-like wrinkles radiated from each corner of her mouth A nodular but fairly symmetrical enlargement of both lobes of the thyroid was noted One pea-sized, moveable lymph node was palpable in the right supraclavicular fossa All upper teeth had been removed, a few worn teeth remained in the lower jaw The buccal mucous membranes were dry, the tongue surface was notably smooth as in atrophy of the lingual papillae There was no evidence of paralysis of any of the cranial nerves The skeletal reflexes were unchanged The abdomen was scaphoid in contour The thorax was moderately hyperresonant The heart sounds were faint, there was a systolic murmur of low intensity and short duration heard over the apex The blood pressure was 138 systolic and 96 diastolic

In the presence of the physician, the patient seemed unable to initiate the act of swallowing At each attempt, after bobbing her head a few minutes, she sought to expectorate soft food and water alike In the fluoroscopic room, the thick barium mixture accumulated in a peculiar round mass, the size of a golf ball, immediately below the level of the cricoid cartilage The patient was unable to move the bolus farther and, after being subjected to strong reassurance and persuasion for five minutes, regurgitated the mass She could not be induced to attempt to swallow the barium again When an effort was made by one of us (T M G) to pass the eso

phagoscope the instrument was firmly grasped in the upper esophagus. The view obtained was that of a swollen, hyperemic mucosa filling the end of the esophagoscope in every maneuver and, with the degree of force considered safe, the endoscope could be passed no farther.

The urine contained a trace of albumin. The blood had a hemoglobin value of 56 per cent (Sahl), 3,720,000 erythrocytes per cubic millimeter, and a negative Kahn reaction.

The patient was fed twice daily for four days by gavage through a heavy Ewald aspirator tube. In the first feedings the tube had to be forced through the upper

FIG 1

esophagus with more than the customary manipulation and pressure. By the third day the Ewald tube could be passed with distinctly less effort. At no time was free hydrochloric acid found (histamine was not used). The patient expectorated large amounts of mucoid saliva, requiring a cup constantly at her bedside. After the fourth day in the hospital she could swallow both soft food and liquids, the former more readily. The patient gained in strength and left the hospital January 25, eight days after admission, with instructions to take seven grains of reduced iron three times each day.

After seeming to improve for four days at home, the patient, on January 29, suddenly became very faint, dizzy, and fell to the floor. She had to be helped to her bed by her daughter. There was no loss of consciousness and no evidence of paresis of any extremity. After an hour in bed, she was well enough to be up and about the bedroom again but she complained of a vague abdominal discomfort.

She was given an enema and returned a tarry, offensive stool. During the night she made, alone, two trips to the bathroom. It is not known whether she defecated. The following morning the patient ate a small breakfast and again complained of marked dizziness and weakness. An hour or so after breakfast, she vomited a moderate amount of dark coffee-ground material which her daughter, a graduate nurse, recognized as blood. The patient made a 15 mile trip by ambulance to the hospital, losing consciousness five minutes before admission. Within an hour she had ceased breathing.

FIG 2.

A postmortem examination was started 30 minutes after death. There was a minimal quantity of panniculus adiposus. The distended intestinal loops were speckled fairly generally with subserous hemorrhages, 2 to 15 mm in diameter. The small intestine yielded 500 cc of clotted blood and bloody fluid. An equal quantity was found in the stomach. Innumerable bleeding points, not over 2 mm in diameter, were present in the mucosa of the upper jejunum, duodenum and stomach. No other lesion could be demonstrated in the abdominal viscera save for recent hemorrhages into both adrenal glands. The spleen was small, the liver of average size.

The heart weighed 290 grams. There were a few atheromatous plaques in the proximal aorta. The coronary arteries were patent. The mitral valve leaflets were scarred and fused so as to admit but one finger into the valve. The mitral annulus measured 70 cm in circumference. Other cardiac measurements were normal. The lungs showed no significant alteration.

In the lumen of the esophagus at its lower end was one-half of an insufficiently masticated stewed prune. There was no obstruction at the cardia. The inner surface of the upper half of the esophagus was hyperemic and had numerous irregular areas, 4 to 10 mm across, which were denuded of mucosa. There was no demonstrable obstruction. The entire esophagus, with the tongue and stomach attached, was removed for examination. The thyroid lobes were each approximately 3 by 3 by 5 cm, extended posteriorly beyond the trachea and left definite imprints upon the lateral surfaces of the collapsed esophagus. The surfaces made by cutting the thyroid revealed small cysts and areas of calcification in the substance of the gland.

FIG 3

FIGS 1, 2, 3 Representative sections from the esophagus showing cellular infiltration, excessive development of mucous glands, denudation of epithelium and hypertrophy of the *muscularis externa*

Microscopic Examination Sections from the liver and spleen showed no change in structure. The wall of the stomach and small intestine had areas of hemorrhage beneath the epithelial lining, occasionally under the serosa and in the smooth muscle, but presented no other recognized change.

Mucous glands were plentiful in the sections from three blocks of tissue taken from the wall of the inflamed upper end of the esophagus. Cardiac type glands were scarce. There was no keratinization of the stratified squamous epithelium. The mucous and submucous layers were not atrophied but broken and denuded areas were clearly evident. Numerous oval islands (1 by 2 by 3 mm), predominantly of lymphocytes but with scattered plasma cells and polymorphonuclear leukocytes, lay beneath the epithelium. The muscular wall was of increased width, varying

from 3 to 6 mm, and showed excess fatty areolar tissue between the irregularly interlacing longitudinal and circular fascicles of striated muscle. Staining by Bielschowsky's silver method revealed no obvious change in the ganglia or fine network of nerves.

Dr G W Rake,²¹ who, with Hurst, originally described lesions in Auerbach's plexus at the middle and lower levels of the esophagus from patients having long standing achalasia of the cardia, has been kind enough to examine representative sections from the case under consideration. He stated in a personal communication, "I can find no lesions of the plexus or nerves. This, of course, does not rule out such lesions entirely since in milder degrees of achalasia one may find many normal Auerbach's plexuses to one abnormal one. My experience with cases of the Plummer-Vinson syndrome has been limited, but the one case which I have examined with care microscopically showed no lesions of the nervous mechanism."

The authors are likewise indebted to Dr Walter Brandes of the Pathological Institute of the University of Tennessee who, after examining the sections, reported, "A definite inflammatory reaction is present with moderate fibrosis and infiltration with lymphocytes. Also an infiltration with fat seems to be present in some areas in the musculature. It seems to me there are a rather large number of mucous glands present. They are unaltered except that in some areas there is a chronic inflammatory reaction as mentioned. The nerves that are seen in the sections I do not feel are noticeably altered. I do believe there is definite chronic esophagitis with erosion of the epithelial lining."

SUMMARY

The particularities of the syndrome of dysphagia and anemia, as observed by many authors, are noted. There is no proved pathological basis for the disorder. As such patients rarely come to the postmortem table, detailed gross and histological findings in one available case seem to be of more than passing interest.

Acknowledgment is made to Dr Angus K Wilson, Davis Memorial Hospital, for preparation of the sections and to Mr Boyers M Clark, Elkins, West Va, for the photomicrographs.

EDITORIAL

PULMONARY EMBOLISM

IF anything is to be accomplished in the prevention and treatment of pulmonary embolism, several things are necessary. A much keener appreciation of its frequency, a knowledge of the chief circumstances that favor its occurrence, an ability to recognize it in its mild and nonfatal forms, and an aggressive and systematic program aimed at prevention, are essential minimal requirements.

The incidence of fatal pulmonary embolism in unselected consecutive postmortem examinations is above 2 per cent^{7, 13}. Pulmonary embolism accounts for from 5 to 6 per cent of deaths following surgical procedures^{12, 13}. In McCartney's series it accounted for about 5 per cent of deaths in parturition, for 3.32 per cent of deaths following trauma, and for slightly less than 2 per cent of all medical deaths¹³.

While the cause or causes of pulmonary embolism are still unknown, valuable studies have been made which indicate important factors in its production. Some of these seem capable of being attacked. These studies serve to identify the circumstances under which pulmonary embolism is likely to occur, and they thus permit us to concentrate our efforts on these groups. Pulmonary embolism is encountered chiefly in patients over 40 years of age². Abdominal surgery in general, and certain types of abdominal operations in particular, predispose to pulmonary embolism². Fatal pulmonary embolism is approximately twice as common among patients with cardiac disease as among patients with normal hearts^{5, 13}. Obesity has been shown to be an important factor predisposing to fatal pulmonary embolism¹³.

Pulmonary embolism rarely is due to detachment of the thrombus of thrombophlebitis². Conversely, when pulmonary embolism occurs, seldom are there signs of peripheral phlebitis. The commonest sites of thrombi giving rise to emboli are, in order of frequency, the iliac vein, the femoral vein, the pelvic veins, the prostatic plexus, the vena cava, and the right auricle¹². The infrequency with which an embolus arises in an upper extremity is striking in contrast to the lower extremity. The effect of gravity, and the much greater motility of the upper extremity, maintaining good venous pressure and promoting good venous blood flow, must be of paramount importance in accounting for this difference. Infection in the pelvic veins, thrombi produced by operations on the pelvic structures, which may extend into larger adjacent veins, and the fact that the venous return flow in the lower extremities is the first to suffer in any impairment of the circulation,⁶ are other factors accounting for the incidence of thrombosis in the lower extremities.

No exact knowledge is available to indicate the time at which a thrombus forms after operation. One suspects that the first 48 hours is a fruitful

period for thrombus formation. The systemic blood pressure is usually lowest during that period. Maximal immobilization of the trunk and legs occurs then. Fever, in itself capable of increasing the circulatory rate, usually is slight or has not appeared during that period. Can an embolus formed at that time be in situ for eight to ten days, the usual date at which fatal pulmonary embolism occurs? It is possible that during that period the embolus is slowly increasing in size, and because of its size and the increased force of the venous flow attendant upon increased activity at the eighth or tenth day, it is carried to the lung. On the other hand it may be that changes in the blood favoring coagulation⁸ reach their maximum from the sixth to the tenth day and determine the time of thrombosis and embolism. Actually, a combination of the factors of slowed venous return and alterations in the coagulating properties of the blood may constitute the most reasonable explanation.⁸

It is customary to regard marked dyspnea and cyanosis as the classical signs of pulmonary embolism. Dogmatic adherence to this conception results in failure to recognize many instances of this complication. Pulmonary embolism manifests itself frequently by the picture of shock. This is characterized by faintness, pallor, sweating, acceleration of the pulse, a marked fall in blood pressure, and sometimes by vomiting and collapse. A brief experience with pulmonary embolism teaches one that fatal attacks are preceded very frequently by milder, nonfatal seizures. The recognition of these premonitory attacks furnishes an incentive to vigorous attempts to prevent further attacks, and to increased caution in the patient's subsequent management. Certain electrocardiographic changes have been described which may assist greatly in the diagnosis of pulmonary embolism, and especially in its differentiation from acute coronary thrombosis^{3, 4, 14}. The patient who gives a history of previous pulmonary embolism following an operation calls for unusual care following subsequent surgical procedures. Even more than special categories of patients shown previously to have a high degree of liability to embolism, this group of patients with premonitory seizures warrants the most intensive studies in prevention.

On the basis that impaired venous circulation plays an important rôle in the occurrence of pulmonary embolism, the following postoperative regimen has been instituted by Gray and MacKenzie¹¹. The patient is placed in the Trendelenburg position for the first 24 hours after operation. Frequent inhalation of carbon dioxide, day and night during the first 48 hours, is instituted. Deep breathing exercises and encouragement of coughing are stressed. Extreme care is taken to keep the patient's legs warm at all times. Frequent massage of the legs is practiced during the first 48 hours and twice daily thereafter until the patient is out of bed. Passive and active movements of the extremities are carried out frequently during the time the patient is in bed. Attention to these details is especially important during the first 48 hours after operation. Experience to date¹

with this program encourages the belief that it is effective in preventing fatal pulmonary embolism *

The occurrence of a mild attack would seem to be a favorable setting for a trial of heparin. Whether a previous mild attack constitutes a contraindication to the continuation of the foregoing postoperative program, time alone will tell.

Why does death occur from pulmonary embolism? Arterial obliteration and insufficiency of the pulmonary circulation in the area involved are not satisfactory explanations. Reflex sympathetic inhibition was regarded by Villaret, Justin-Besancon and Bardin¹⁷ as being an important mechanism. Gosset, Bertrand and Patel¹⁰ submitted evidence that an embolus lodged in a peripheral vessel is fixed by arterial spasm. The rôle such a mechanism plays in the arterial insufficiency in arterial embolism has been discussed at length by McKechnie and Allen¹⁵. Is it not possible that pulmonary embolism results in spasm of some or all of the pulmonary arteries, thus explaining in part its serious consequences? On this ground, and on the basis of favorable results seen from its administration in embolic occlusion of the peripheral arteries,^{1,9} papaverine hydrochloride, grains $\frac{1}{2}$, might justifiably be administered intravenously immediately after a seizure suspected of being pulmonary embolism.

There are many unknowns in this complex problem, and this seems to have given rise to a feeling of impotency in attacking the situation that has stifled progress. There is reason to hope that if we utilize such knowledge as we now possess, as well as the results of future investigations, means will be found to diminish greatly this menace.

REVIEWS

Heart Failure By ARTHUR M FISHBERG, M D, Associate in Medicine, Mount Sinai Hospital, New York City 788 pages, 15.5 × 24 cm Lea and Febiger, Philadelphia 1937 Price, \$8.50

It is of course impossible to review in detail the subject matter of a book of this size. In 37 chapters the author discusses the phenomena of heart failure, peripheral circulatory failure and what he chooses to call hypodiastolic failure. In this last group are included those instances of inadequate diastolic filling of the heart such as may occur in pericarditis or tachycardia. In general he follows a scheme in which a symptom is described, the circumstances under which it occurs are explained, and the mechanisms involved in its production are discussed, descriptions of pathological anatomy are included when indicated. Left- and right-sided heart failure and failure initiated by "generalized cardiac strain" are discussed separately. The treatment of heart failure in general and in its special manifestations is discussed in further chapters. The literature pertaining to various aspects of the problems discussed has been reviewed and a bibliography is placed at the end of each chapter.

If it is kept in mind that further knowledge may modify the opinions expressed, this volume should serve excellently as a rather detailed examination of the subject.

W S L, JR

External Diseases of the Eye By D T ATKINSON, M D, F A C S Second Edition 718 pages, 15.5 × 24 cm Lea and Febiger, Philadelphia 1937 Price, \$8.00

This book, revised by the author, is the second edition, the first having been published by Lea and Febiger in 1934. Like the original, this edition is not limited to external diseases of the eye but includes those other conditions which may be diagnosed without the aid of the ophthalmoscope. The contents are divided into 15 chapters. Included in the chapter on diseases of the orbit is a consideration of nasal and sinus diseases which may secondarily involve the eye. As in the first edition many of the illustrations are of wax models, and while the majority of these are quite good, photographs of the actual lesion, especially if in stereopticon, would give a much better impression of the condition.

Valuable additions include description of slit-lamp microscopy, orthoptic training, allergic manifestations and some of the newer surgical procedures. Also included but rather underrated in value is the iridencleisis operation for glaucoma.

To the student, the general practitioner and the ophthalmologist this book certainly can be recommended.

H F G

Appendicitis, a Clinical Study By W H BOWEN, Hon M A (Camb), M S (Lond), F R C S 201 pages, 13 × 19 cm Cambridge University Press, London, Macmillan Co, New York 1937 Price, \$2.50

An interesting monograph by an English surgeon on acute and chronic appendicitis. The author advises immediate operation in the acute stage and sets up definite rules to govern the decision as to operation in the chronic stage. The author rightly stresses the importance of a knowledge of the macroscopic pathology of the appendix. The monograph is well written but does not constitute an important advance.

T R A

Handbook of Orthopaedic Surgery By ALFRED RIVES SHANDS, JR., B A., M D
593 pages, 15 × 24 cm C V Mosby Company, St Louis 1937 Price, \$5 00

This book by Dr Shands has been compiled to act as a ready reference book for advanced students and practitioners so that concise information may be at hand. No attempt has been made to go into details of description and analysis of the many problems, but rather to give the essentials of all orthopaedic conditions and to allow the investigator to proceed further in articles referred to in the bibliography. If this book is used for students in school, explanatory lectures should be used to supplement it. The bibliography is quite general and complete and offers opportunity for further intensive study of any subject.

A F V

Textbook of Diagnostic Roentgenology By LEWIS J FRIEDMAN, M D 623 pages,
17 × 25 cm D Appleton-Century Co., New York 1937 Price, \$10 00

This volume attempts to cover the whole field of diagnostic roentgenology and hence deals with each aspect in too brief a fashion to serve the purpose of the man specializing in that field. It is perhaps best suited to give the physician in general practice a survey of the whole subject.

The viewpoint is consistently maintained that the roentgenologist is a medical consultant and should be in possession of all available clinical data before rendering his opinion.

W L K

Carcinoma of the Female Genital Organs By M C MALINOWSKY, and E QUATER
Translated from the Russian by A S Schwartzmann, A B., M D 255 pages,
15.5 × 23.5 cm Bruce Humphries, Inc., Boston 1936 Price, \$5 00

This work is a rather superficial one covering all phases of carcinoma of the female sexual organs. It is contributed to by eleven different authors, and contains much interesting statistical data compiled chiefly from the European clinics and from the works of outstanding European investigators. It is interesting to note throughout this work the similarity of the treatment of these types of carcinoma in Europe and in this country. It is surprising, however, that no mention is made of the use of spinal alcohol injections in the treatment of pelvic pain in far advanced cases.

The chapter on the "Clinical Picture of Carcinoma of the Uterus" by Dr Quater, and the one on "Metastatic Carcinoma of the Ovaries" by Dr Pojarissky are particularly good. The last chapter in the book deals with carcinoma of the female sexual organs from the viewpoint of disability and social insurance. The illustrations throughout the book, especially the microphotographs, are quite poor.

This work would be much more valuable if it were more exhaustive.

COLLEGE NEWS NOTES

NOMINATIONS, 1938-39

Elective Offices

Dr William J Kerr, President-Elect, San Francisco, Calif, accedes to the Presidency

New Nominations

| | |
|-----------------------|-------------------------------------|
| President-Elect | O H Perry Pepper, Philadelphia, Pa |
| First Vice-President | James B Herrick, Chicago, Ill |
| Second Vice-President | Noble Wiley Jones, Portland, Oregon |
| Third Vice-President | Charles T Stone, Galveston, Tex |

Respectfully submitted,

Committee on Nominations,
JONATHAN C MEAKINS, *Chairman*

NOTICE OF AMENDMENT TO THE BY-LAWS

In accordance with the present By-Laws of the American College of Physicians and by direction of the Board of Regents at a regular meeting held on April 18, 1937, notice is hereby given to the Fellows and Masters of the College that the following amendment to the By-Laws has been approved by said Board of Regents and will be presented for adoption or rejection at the Annual Business Meeting to be held in New York City April 7, 1938

(An addition to the By-Laws, Article IV, Section 1, to be added as an additional paragraph)

"Any member of the Board of Governors unable to attend the Annual Session shall appoint as his alternate, with all the privileges of a Governor, a Master or Fellow of his district who will be in attendance at that Session Upon presentation to the Chairman of the Board of Governors of a certificate of appointment, the alternate shall be recognized and act in the full capacity of Governor for the Session to which he has been appointed The same alternate shall not be appointed for more than two consecutive years "

NEW LIFE MEMBERS

The following Fellows have been entered, upon their subscriptions, as Life Members of the American College of Physicians, at the dates indicated, making a total of ninety-four

Dr Louis H Fligman, Helena, Mont, January 10, 1938
Dr Max H Weinberg, Pittsburgh, Pa, January 13, 1938
Dr W P Anderton, New York, N Y, January 13, 1938
Dr Orrin Sage Wightman, New York, N Y, January 15, 1938
Dr J Dorwin Mabey, Montclair, N J, January 15, 1938
Dr Robert L Levy, New York, N Y, January 15, 1938
Dr Harry S Emery, Portland, Maine, January 17, 1938
Dr Alex M Burgess, Providence, R I, January 18, 1938

- Dr Theodore S Bacon, Springfield, Mass, January 19, 1938
 Dr Mary Riggs Noble, Bowmansdale, Pa, January 24, 1938
 Dr Mary Elizabeth Bass, New Orleans, La, January 24, 1938
 Dr Karl Vogel, New York, N Y, January 25, 1938

GIFTS TO THE COLLEGE LIBRARY

Grateful acknowledgment is made of the receipt of the following donations to the College Library of publications by members

Books

- Dr Linn J Boyd (Fellow), New York, N Y—"A Study of the Simile in Medicine",
 Dr Thomas Hall Shastid (Fellow), Duluth, Minn—"Tramping to Failure" and "How to Stop War-Time Profiteering",
 Dr William D Stroud (Fellow), Philadelphia, Pa, co-author with Dr Lawrason Brown (Fellow, deceased), Dr George R Minot (Fellow), Dr William B Castle (Fellow), Dr George B Eusterman (Fellow) and Dr George F Dick—an autographed copy of each of the 1934, 1935 and 1936 "Year Book of General Medicine",
 Dr Russell M Wilder (Fellow), Rochester, Minn—an autographed copy of "A Primer for Diabetic Patients",
 Dr Lowell S Selling (Associate), Detroit, Mich—"Diagnostic Criminology"

Reprints

- Major Joseph R Darnall (Fellow), (MC), U S A—2 reprints,
 Dr Ralph M Fellows (Fellow), Osawatomie, Kan—2 reprints,
 Lt Col Arthur R Gaines (Fellow), (MC), U S A—1 reprint,
 Dr Paul John Hanzlik (Fellow), San Francisco, Calif—51 reprints,
 Dr Edward G Huber (Fellow), Boston, Mass—1 reprint,
 Dr George Morris Lewis (Fellow), New York, N Y—25 reprints,
 Dr James L McCartney (Fellow), Catskill, N Y—1 reprint,
 Dr Joseph A Pollia (Fellow), Los Angeles, Calif—14 reprints,
 Dr Thomas Hall Shastid (Fellow), Duluth, Minn—2 reprints,
 Dr Virgil E Simpson (Fellow), Louisville, Ky—1 reprint,
 Dr Walter M Simpson (Fellow), Dayton, Ohio—3 reprints,
 Dr Wilham L Smith (Fellow), New Orleans, La—1 reprint,
 Dr Felix Cunha (Associate), San Francisco, Calif—10 reprints,
 Dr Herbert R Edwards (Associate), New York, N Y—4 reprints,
 Dr Hyman I Goldstein (Associate), Camden, N J—1 reprint,
 Dr John M Nicklas (Associate), Valhalla, N Y—2 reprints,
 Dr Lowell S Selling (Associate), Detroit, Mich—18 reprints

Dr C W Waddell (Fellow), Fairmont, W Va, has contributed two original copies of the "Annals of Medicine," Volume I, Nos 1 and 2, to the permanent archives of the College These were the first two journals sponsored and published by the College

Grateful acknowledgment is also made of the receipt of the following gifts

- Mr and Mrs James Inglis, Ann Arbor, Mich—1 book, "The Collapse Therapy of Pulmonary Tuberculosis" by John Alexander, M D

Metropolitan Life Insurance Company, New York, N Y—1 book, "Twenty-Five Years of Health Progress, A Study of the Mortality Experience Among the Industrial Policyholders of the Metropolitan Life Insurance Company, 1911 to 1935"

SECTIONAL MEETING OF ARKANSAS MEMBERS

Dr Oliver C Melson (Fellow and Governor for Arkansas) reports that the Fellows and Associates of the American College of Physicians of Arkansas met at the Albert Pike Hotel in Little Rock on November 8 Dr John H Musser (Fellow), New Orleans, was the guest speaker Those present included Dr H T Smith of McGehee, Dr F N Gordon of Fayetteville, Dr George B Fletcher, Dr A G Sullivan and Dr Euclid Smith of Hot Springs, Dr Charles T Chamberlain of Fort Smith, Dr L D Massey of Osceola, Dr J D Riley of State Sanatorium, Dr A A Blair of Fort Smith, Dr J N Compton, Dr John R Dibrell and Dr Oliver C Melson of Little Rock

Such state meetings will be inaugurated as a yearly feature in Arkansas

Dr John G Young (Fellow), Dallas, Tex, is President of the Texas Pediatric Society and of the Dallas Pediatric Society Dr Young is also Consultant to the Dallas Tuberculosis Association and Chief of the Medical Staff of Freeman Memorial Clinic for Children

Dr Howard S Brasted (Fellow), Hornell, N Y, addressed the Pre-Medic Club of Houghton College recently on "Blood Transfusions and Blood Typing"

Dr J W Torbett, Sr (Fellow), Marlin, Texas, gave a lecture on "Undulant Fever of the Chronic Types" before the Brown-Mills and San Saba County Medical Society meeting in November Dr Torbett is director and one of the founders of the Marlin Hot Wells Foundation, which recently established the Crippled Children's Hospital and Hot Water Pool in Marlin, Texas

Dr E W Gehring (Fellow and Governor for Maine), having recently resigned as Chief of Medical Service of Maine General Hospital at Portland, has been succeeded by Dr E H Drake (Fellow)

Dr B S Pollak (Fellow) is the medical director of the new Hudson County Tuberculosis Hospital and Sanatorium, newest unit of the Jersey City Medical Center This hospital, towering some eighteen or twenty stories, will accommodate 510 patients In equipment, furniture and facilities, nothing has been spared to make the institution one of the most complete in the country

At the Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association, to be held in Chicago, February 14 and 15, 1938, the following Fellows of the College will participate

- Dr Willard C Rappleye, Dean of Columbia University College of Physicians and Surgeons, New York City, "The Functions of the Special Examining Boards",
- Dr Burrell O Raulston, Professor of Medicine, University of Southern California School of Medicine, Los Angeles, "An Introduction to Clinical Medicine and Some Variations in the Curriculum of the Third and Fourth Years in Medical School",
- Dr J G FitzGerald, Director of the School of Hygiene and Connaught Laboratories, University of Toronto, Toronto, Ont, Canada, "Medical Student Instruction in Preventive Medicine",
- Dr John H Musser, Professor of Medicine, Tulane University of Louisiana School of Medicine, New Orleans, and Dr James D Bruce, Director of the Department of Postgraduate Medicine, University of Michigan, Ann Arbor, participants in the Symposium on Graduate Medical Education
-

Dr Herbert L Bryans (Fellow), Pensacola, Fla, has been elected President of the Gulf Coast Clinical Society

The Bronx Hospital of New York City sponsored a series of afternoon lectures for physicians during November and December Dr Alvan L Barach (Fellow), New York City, presented an address on "Peripheral Circulatory Failure and Acute Pulmonary Edema Occurring as Complications in Pneumonia", Dr Elliott P Joslin (Fellow), Boston, "Diabetes Mellitus", and Dr Russell L Cecil (Fellow), New York City, "Chronic Arthritis"

Dr Samuel M Bittinger (Fellow) has been appointed assistant superintendent and medical director of the new sanatorium for the treatment of tuberculosis at Black Mountain, N C

The Commonwealth Fund of New York has approved a grant of \$10,857 annually for three years to Western Reserve University School of Medicine, Cleveland, especially for research on chronic nephritis by Dr Joseph M Hayman (Fellow), who is associate professor of medicine

At the last annual meeting of the Medical Society of the State of Pennsylvania, the Board of Trustees and the past presidents presented to Dr Walter F Donaldson (Fellow), Pittsburgh, Secretary of the Society for many years, an oil portrait of himself Dr Arthur C Morgan (Fellow), Philadelphia, made the presentation address

Dr William Egbert Robertson (Fellow), Philadelphia, presented an address, "Dr Rush and the Signers of the Constitution," before the Philadelphia County Medical Society on the occasion of the marking of the one hundred and fiftieth anniversary of the signing of the Constitution of the United States

Dr Charles S Holbrook (Fellow), New Orleans, has been elected President-Elect of the Southern Psychiatric Association

Dr Priscilla White (Fellow), Boston, addressed the fifth annual scientific meeting of the Georgia Pediatric Society at Atlanta on December 9 on "Endocrine Problems in Juvenile Diabetes, Recent Problems in Juvenile Diabetes"

Dr George G Onstein (Fellow), New York City, delivered a paper on "The Pathogenesis of Pulmonary Tuberculosis from the Physician's Point of View" in connection with the fall graduate conferences of the Wayne County (Michigan) Medical Society, the Detroit Department of Health and the Detroit Tuberculosis Sanatorium

Dr Irving S Wright (Fellow), New York City, was a guest speaker at the annual "Scientific Day" of Montefiore Hospital, Pittsburgh, recently, his address being on "A Critical Analysis of Recent Advances in the Study of Vascular Disease"

Dr David P Barr (Fellow), St Louis, Dr Russell L Cecil (Fellow), New York City, Dr Alfred Friedlander (Fellow), Cincinnati, Dr Ernest E Irons (Fellow), Chicago, and Dr Roger I Lee (Fellow), Boston, are members of the Advisory Committee on Pneumonia Control, recently appointed by Dr Thomas Parran (Fellow), Surgeon General of the U S Public Health Service

Dr Charles C Bass (Fellow), Dean of Tulane University of Louisiana School of Medicine, delivered the principal address at the recent dedication of the Rudolph Matas Medical Library, which is the library of Tulane University of Louisiana School of Medicine, named in honor of Dr Rudolph Matas, Emeritus Professor of Surgery at the University

Dr Henry A Christian (Fellow), Boston, Mass, was one of the speakers at the dedication of the new building of the Syracuse University College of Medicine, Syracuse, N Y, on November 22

Dr Clarence E de la Chapelle (Fellow), New York City, is acting chairman of the Department of Medicine of the New York University College of Medicine

Dr James Edward Hubbard (Associate), is the director of the Huntington (W Va) Radium and X-Ray Clinic, which recently opened new quarters in the Memorial Hospital at Huntington

Dr Lee Rice (Fellow), San Antonio, Texas, has been elected a vice-president of the Southern Medical Association

Among speakers from the United States on the seventh cruise congress of the Pan American Medical Association, which left New York City January 15 were the following

- Dr Edwin C Ernst (Fellow), St Louis, "Recent Developments in Relation to the Radiation Management of Cancer",
Dr Howard R Hartman (Fellow), Rochester, Minn, "Treatment of Hemorrhagic Ulcer of Stomach or Duodenum",
Dr Herman N Bundesen (Fellow), Chicago, Ill, "Amebiasis"
-

The Section on the Medical Sciences of the American Association for the Advancement of Science devoted its entire program, December 27 to January 1, to a symposium on syphilis. The following were contributors:

- Dr John A Kolmer (Fellow), Philadelphia, "Serologic Reactions in Relation to Infection and Treatment of Syphilis",
Dr Paul A O'Leary (Fellow), Rochester, Minn, "Neurosyphilis",
Dr Walter M Simpson (Fellow), Dayton, Ohio, "High Temperatures",
Dr Dudley C Smith (Fellow), University, Va, "Untoward Reactions—Intercurrent Infections",
Dr Thomas Parran (Fellow), Washington, D C, "Syphilis A Public Health Program"
-

Dr Solomon Strouse (Fellow), formerly of Chicago, has been appointed Associate Clinical Professor of Medicine at the University of Southern California Medical School at Los Angeles

As a recognition of his medical and public health services to Cuba, the Order of Merit of Carlos Finlay was recently conferred upon Dr Edgar Mayer (Fellow), New York City

Dr C C Carpenter (Fellow), Dean of the Wake Forest Medical School, will be the director of the new school of medical technology, recently announced by Wake Forest College and the Rex Hospital, of Raleigh, N C

Dr O H Perry Pepper (Fellow), Philadelphia, was a guest speaker and guest clinician on the program of the William Moore Guilford Clinic, a newly organized graduate clinic day, observed by the Good Samaritan Hospital, Lebanon, Pa, and the Lebanon County Medical Society, each year during the week of Dr Guilford's birthday. Dr Guilford reached the age of 105 years on November 26, 1937

Dr C Lydon Harrell (Fellow), Norfolk, will serve as medical adviser of the new Tidewater Victory Memorial Hospital for the treatment of tuberculosis near Norfolk

Dr Herbert Z Giffin (Fellow), Professor of Medicine in the University of Minnesota Graduate School of Medicine, has been elected President of the Staff of the Mayo Clinic

Dr G Harlan Wells (Fellow), Philadelphia, has been elected President of the Homeopathic Medical Society of Pennsylvania

OBITUARIES

DR LAWRASON BROWN

Dr Lawrason Brown (Fellow) died at his home in Saranac Lake, December 26, 1937, at the age of sixty-six. He had been ill at periods for the past several years with symptoms traceable to longstanding pulmonary tuberculosis. Mrs. Brown survives him.

Dr. Brown was born in Baltimore, September 29, 1871, and there received his education. Johns Hopkins gave him the A. B. degree in 1895, and the M. D. in 1900. He soon went to Saranac Lake where he came under the influence of Trudeau. Assuming the duties of resident physician at the Trudeau Sanatorium in 1901, his great energy, efficiency and intelligence were released to build on the foundation which Trudeau had labored to lay. With zeal that grew from the spirit of truth within him and throve in the atmosphere of humaneness about him, Brown perfected the plan of treatment of tuberculous patients in the sanatorium, organized the records, instituted a follow-up system which in later years yielded rich clinical studies, and furthered scientific study in the laboratory and clinic. He soon became a leader among that remarkable group of physicians who made Saranac Lake a fountain head of knowledge of tuberculosis and established a standard of clinical practice which was the pattern for the country. The national antituberculosis campaign was gaining momentum and, as a part of this, the need for sanatoria became more and more apparent, largely on account of what was being demonstrated at the Trudeau Sanatorium. As these were established throughout the country, Brown's influence spread afar. He conceived the idea of organizing physicians engaged in sanatorium work, and this fructified in the creation of the American Sanatorium Association, now grown to be the most important society of its kind in the country. He established and edited the *Journal of the Outdoor Life*, bringing to tuberculous patients the essential facts of hygiene and proclaiming the creed of acquiescence and hope which is a vital part of the "cure." For thousands of these patients his "Rules for Recovery from Tuberculosis" was and still is a lamp in the darkness. An unfailing scientific curiosity constantly renewed his energy which he spent freely in discussions with his confreres at informal and formal meetings, in teaching, and in writing numerous articles for periodicals, books and systems of medicine, as well as longer monographs. It was his habit always to keep testing and retesting medical principles, mostly in the light of the Trudeau follow-up system and its revelation of the ultimate fate of his former patients, the result of which was a progressive refinement of the understanding of the behavior of tuberculosis and its diagnosis and treatment. The soundness of his understanding, the honesty of his thinking, and the quality of his leadership won for Brown a degree of respect and distinction enjoyed by few in their chosen medical fields. His long experience and deep knowledge enabled

him to evaluate better than most physicians the factors which aid the healing of tuberculosis, and among these he always assigned a high place to the *vis medicatrix naturae*. He deprecated ignorance of the possibilities of rest treatment and the fallacy of attempting to displace it completely with "collapse" therapy, though he did not underrate the latter. Rather, he exemplified that discriminating judgment in selecting a plan of treatment for the individual patient which marks the seasoned clinician.

At the time of his death, Dr. Brown was consultant to the Trudeau Sanatorium and the Waverly Hills Sanatorium, Louisville, Ky., also a trustee of the Trudeau Sanatorium, the New York State Hospital at Ray Brook, and the Potts Memorial Hospital, Livingston, N. Y., and a member of the advisory council of the Henry Phipps Institute, Philadelphia. He had been president of the American Sanatorium Association, American Clinical and Climatological Association, and the National Tuberculosis Association. He was a fellow and life member of the American College of Physicians, and a member of the Association of American Physicians, the American Association of Thoracic Surgery, and of other organizations. He received the Trudeau medal from the National Tuberculosis Association in 1933. He was awarded the honorary degree of doctor of science from Dartmouth College in 1931 and from the Medical College of Virginia in 1936.

Lawrason Brown had the devotion of his patients, the respect of his professional brethren, and the love of his friends.

J. BURNS AMBERSON, JR., M.D., F.A.C.P.

DR. JOHN LEE

Dr. John Lee of Detroit died September 22, 1937, after a long illness.

Dr. Lee was born in Detroit in 1869, and graduated from the Detroit College of Medicine in 1890. For many years he taught as Assistant Professor of Medicine at his alma mater, his active clinical teaching being done at St. Mary's Hospital, where he served throughout his long professional career as Attending Physician in the Department of Medicine. Dr. Lee served during the Spanish American War. He had been an Associate of the American College of Physicians for many years.

From the time that he started in practice, Dr. Lee devoted a large part of his time to teaching in the wards at St. Mary's Hospital, as well as carrying on a large practice. Energetic and enthusiastic, he enjoyed the warm friendship and respect of the many physicians who owed their clinical training to him during their college careers.

HENRY R. CARSTENS, M.D., F.A.C.P.,
Governor for Michigan

DR ALBERT WARREN FERRIS

Dr Albert Warren Ferris (Fellow), East Orange, N J, died October 4, 1937, following a prolonged illness of encephalitis with a parkinsonian syndrome, at the age of 81

Dr Ferris was born in Brooklyn, N Y, 1856, attended Adelphi Academy of Brooklyn, Newark Academy, Newark Latin School and Hasbronck Institute of Jersey City, A B, New York University, 1878, A M, same, 1885, M D, Columbia University College of Physicians and Surgeons, 1882, interned at Kings County Hospital, Flatbush, L I, 1883-85, assistant and later resident physician, Sanford Hall for Insane, Flushing, N Y, 1885-91, physician-in-charge, Dr Choate's Home for Insane, Pleasantville, N Y, 1906-07, senior resident physician, Glen Springs Sanitarium, Watkins, N Y, 1912-13 and from 1917 to 1930, president, New York State Commission on Lunacy, 1907-11 (appointed by former Governor Charles E Hughes), medical expert and director, Saratoga Springs State Reservation Commission, 1913-16, for some time consulting physician to the Binghamton State and Manhattan State (N Y) hospitals, also during his earlier career, Assistant in Neurology, Vanderbilt Clinic, Columbia University, 1893-1900, member, Phi Beta Kappa and Delta Upsilon fraternities (national first vice president of latter in 1884 and in 1902), member and ex-vice president, ex-editor of journal and a delegate to the American Medical Association from the Medical Society of the State of New York, Fellow and ex-chairman of a section, New York Academy of Medicine, member, American Psychiatric Association, Fellow, American Medical Association, member of various New York county medical societies, according to his residence at the time, author of many articles in national medical journals and of over 250 articles appearing in the International Encyclopedia and in the International Year Book, Fellow of the American College of Physicians since 1920

Dr Ferris is survived by a brother, Mr Richard Ferris, New York City
Seldom does one see more evidence of a fruitful professional life His career was an honor to the medical profession and to the College

CLARENCE L ANDREWS, M D, F A C P,

Governor for New Jersey

DR E MARK HOUGHTON

Dr E Mark Houghton of Detroit, Michigan, died December 12, 1937

Born in 1867, he was educated at the University of Michigan, where he received his Ph C degree in 1893, and M D in 1894 After further work in pharmacology, he joined the staff of Parke, Davis and Company in 1895, where he became director of medical research and biological laboratories He held this position until 1929, when he was made consulting director

Besides membership in the Wayne County Medical Society, Detroit

Medical Club, Michigan State Medical Society, and American Medical Association, he held membership in the Society of American Bacteriologists, American Pharmaceutical Association, Society of Immunologists, National Tuberculosis Association, and in 1910 was a delegate to the United States Pharmacopoeia Convention. Dr. Houghton had been a Fellow of the American College of Physicians since 1921.

Enjoying a high reputation for work in his professional field, Dr. Houghton was also a genial friend to his many professional colleagues. A scholarly gentleman, he will be greatly missed by his many friends both in the profession and the laity.

HENRY R. CARSTENS, M.D., F.A.C.P.,
Governor for Michigan

DR. HARVEY ELIJAH WELLMAN

On October 20, 1937, Dr. Harvey E. Wellman died at the Jane Brown Memorial Hospital at Providence as the result of an acute duodenitis and enteritis of eight days' duration.

Dr. Wellman, a Fellow of the College (1937), had earned the deep respect and affection of his colleagues and of the patients who had come under his care. Always an earnest and capable clinician, a most conscientious worker in his various hospital assignments, he found time for an interest in the broader aspects of medical study and always had a keen eye for the improvement of the service in the various hospital organizations with which he was connected. During his term as Resident Physician at the Rhode Island Hospital he was particularly interested in the Pathological Laboratory and as a result of his efforts a radical improvement in this department took place. As Assistant Physician in the Division of University Health at Brown University he won the confidence and affection of the student body. During the last few years of his life he became especially interested in diseases of the chest and his place in the Thoracic Clinics of the Charles V. Chapin and Rhode Island Hospitals will be hard to fill.

At the time of his death Dr. Wellman was forty-five years old. He was graduated from Williams College with the degree of A.B. in 1914 and from Harvard Medical School in 1926. He served with the U.S. Navy Base Hospital No. 4 during the World War. He was appointed Assistant Visiting Physician to the Rhode Island Hospital in 1936, Visiting Physician to the Charles V. Chapin Hospital in 1935 and Consulting Physician to the Rhode Island State Infirmary in 1935. He was a diplomate of the National Board of Medical Examiners, the author of a number of published papers and a member of the following organizations: Providence Medical Association, Rhode Island Medical Society, New England Heart Association and American Medical Association.

ALEX. M. BURGESS, M.D., F.A.C.P.,
Governor for Rhode Island

DR HENRY WILLIAM JAEGER

Dr Henry William Jaeger (Associate, 1928), born March 14, 1888, at Washington, D C, died October 21, 1937, at his home in Washington of coronary occlusion

Dr Jaeger was educated in the Public Schools of Washington and at the George Washington University, from which he was graduated in medicine in 1911. He served internships at Casualty Hospital, Washington, and at the German Hospital, Brooklyn, N Y. He was a member of the Medical Society of the District of Columbia, a Fellow of the American Medical Association, and an Associate of the American College of Physicians.

Dr Jaeger was particularly interested in music and was a member of the choir of the Nobles of the Mystic Shrine. During the last years of his life he was tenor soloist at the Washington Cathedral. He had those "mysterious motions of the soul, not to be defined save in strange melodies." Because of its illusiveness, its subtle shades, and its vanishing ecstasies, he found music entrancing.

Keeping abreast of the advances in medicine, Dr Jaeger had a lucrative practice. His patients became his friends, because he had a capacity for a deep and sustained friendship, which he manifested not only when occasion offered, but he sought opportunities to extend to others those little amenities which are precious to all of us. He was admired and loved not only for loyalty to friendship, but also for his integrity of purpose and the sweetness of his nature, and because he was of the company of those who make the barren places fruitful with kindness.

Furnished by courtesy of The Medical Society
of the District of Columbia

DR THOMAS TIPTON WALKER

In the death of Thomas Tipton Walker, the medical profession loses a well qualified pathologist, a keen student of medicine, and one particularly suited to research. He proudly and meticulously followed the precepts of medical ethics and demanded of himself and his colleagues a very high standard of work and achievement. Six published papers attest his scientific interest in medicine. In his hours of recreation, he made the same demands of himself as in his work—to excel in whatever he did.

Dr Walker was born in Atlanta, Georgia, March 11, 1904. He graduated from Emory University in 1924 with the degree of Bachelor of Science, cum laude, and the following year received his Master's degree from the University of North Carolina. He then entered Harvard Medical College and in 1928 a scholarship took him to London, where he worked at St Thomas' Hospital under Sir Cuthbert Wallace.

On graduation from Harvard Medical College, he accepted a residency

in pathology at the Boston City Hospital, and during his stay there he instructed in physiology and pathology at Tufts Medical School until 1931. After postgraduate study abroad at Eppendorfer Krankenhaus and in Frankfurt at the Stadische Krankenhaus, he returned to the United States and accepted a position as pathologist at the Duke Hospital, Durham, North Carolina. While at Durham he was instructor in pathology at Duke University. In 1932 he became director of the Department of Laboratories at the House of the Good Samaritan and Mercy Hospitals, Watertown, New York, later being appointed consulting pathologist at the Jefferson County Sanatorium at Watertown. These positions he fulfilled most efficiently and rendered to Watertown and surrounding communities the highest type of pathological service.

He was diplomate of the National Board of Medical Examiners and also of the American Board of Pathology, a member and officer of the Jefferson County Medical Society, a member of the New York State Medical Society, the American Medical Association, the Association of Pathologists and Bacteriologists, American Society of Clinical Pathologists, the New York State Association of Public Health Laboratories, the Pathological Society of Eastern New York, and an Associate of the American College of Physicians since April 28, 1935.

Dr. Walker died November 13, 1937, and in his untimely death medicine was deprived of a research student who was well qualified to be a leader in the advance of medical science.

He is survived by his widow, Lillie Cutlar Walker.

This obituary was very kindly prepared by Walter S. Atkinson, M.D., of Watertown, New York.

C. F. TENNEY, M.D., F.A.C.P.,
Governor for Eastern New York, New York

PROGRAM
TWENTY-SECOND ANNUAL SESSION
AMERICAN COLLEGE OF PHYSICIANS
NEW YORK, N Y

April 4-8, 1938

GENERAL SESSIONS AND LECTURES

| Commodore, 42d St & Lexington Ave | 7 | 3 50 and up | 5 00 and up |
| Lexington, 48th St & Lexington Ave | $\frac{1}{4}$ | 4 00 and up | 6 00 and up |
| Murray Hill, 41st St & Park Ave | 9 | 4 00 and up | { 3 50 inside room 5 00 outside room |
| Pennsylvania, 34th St & 7th Ave | 20 | 3 50 and up | 5 00 and up |
| Prince George, 14 E 28th St | 22 | 2 25 to 4 00 | 3 50 to 6 00 |
| Roosevelt, 45th St & Madison Ave | 5 | 5 00 and up | 7 00 and up |
| Shelton, 49th St & Lexington Ave | $\frac{1}{4}$ | 3 50 and up | 4 50 and up |

Members should make reservations directly with hotels of their choice. Mention the convention of the American College of Physicians, for rates above quoted are, in many instances, only for this occasion.

WHO MAY REGISTER—

- (a) All members of the American College of Physicians in good standing for 1938 (dues, if not paid previously, may be paid at the Registration Bureau)
- (b) All newly elected members

- (c) House Officers of the hospitals participating in the program, without registration fee, upon presentation of proper identification, exhibits, general sessions and afternoon lectures
- (d) Members of the Medical Corps of Public Services of the United States and Canada, without registration fee, upon presentation of proper credentials
- (e) Qualified physicians who may wish to attend this Session as visitors. Such physicians shall pay a registration fee of \$12 00, and shall be entitled to one year's subscription to the ANNALS OF INTERNAL MEDICINE (in which the proceedings will be published), included within such fee

REGISTRATION BLANKS FOR ALL CLINICS AND DEMONSTRATIONS AND ROUND TABLE CONFERENCES will be sent with the formal program to members of the College. Guests will secure registration blanks at the Registration Bureau during the Session.

TRANSPORTATION—On account of nationwide reductions in railroad fares, there are no convention rates any longer in effect. In many instances, however, reduced round trip tickets are in effect from certain localities. Members should consult their local ticket agents.

The Committee on Transportation will issue full data concerning local transportation at the meeting.

THE GENERAL BUSINESS MEETING OF THE COLLEGE will be held at 11 30 a m, Thursday, April 7, immediately following the general scientific program of the morning. All Masters and Fellows of the College are urged to be present.

There will be the election of Officers, Regents and Governors, the reports of the Treasurer and of the Executive Secretary, the presentation of an amendment to the By-Laws, and the induction to office of the new President, Dr. William J. Kerr, San Francisco, Calif.

BOARD AND COMMITTEE MEETINGS—The following meetings are scheduled as indicated. Special meetings will be announced and posted.

A *special dinner* will be tendered to the Board of Regents by members of the Board of Governors at the Waldorf-Astoria Hotel, Sunday evening, April 3.

COMMITTEE ON CREDENTIALS

Sunday, April 3, 9 00 a m Carpenter Suite, Fourth Floor, Waldorf-Astoria Hotel

BOARD OF REGENTS

Carpenter Suite, Fourth Floor, Waldorf-Astoria Hotel

Sunday, April 3, 2 30 p m

Tuesday, April 5, 12 00 m *

Friday, April 8, 12 00 m *

BOARD OF GOVERNORS

Carpenter Suite, Fourth Floor, Waldorf-Astoria Hotel

Monday, April 4, 5 00 p m

Wednesday, April 6, 12 00 m *

* Buffet luncheon served

SPECIAL FEATURES

MONDAY, APRIL 4, 1938

THE ANNUAL SMOKER will be held in the Ballroom of the Waldorf-Astoria Hotel on Monday, immediately following the evening meeting, at about ten-twenty o'clock. It will be limited to men only. The entertainment will consist of a floor show to be followed by informal singing by the audience. Light refreshments and beer will be served. Fellows and Associates are invited to attend the Smoker as guests of the College.

TUESDAY, APRIL 5, 1938

THEATER NIGHT. Blocks of desirable seats for some of the most popular plays have been reserved. These will be on sale at the Waldorf Ticket Agency, and those desiring to go to the theater are urged to buy their tickets promptly after registering for the Session.

-- -- WEDNESDAY, APRIL 6, 1938

CONVOCATION OF THE COLLEGE—8 30 p m, Grand Ballroom, Waldorf-Astoria Hotel. All Masters and Fellows of the College and those to be received in Fellowship should be present. Newly elected Fellows who have not yet been received in Fellowship are requested to assemble in the West Foyer of the Waldorf-Astoria Hotel (third floor, adjoining west side of the Ballroom) at 7 45 o'clock, preparatory to the formation of the procession. They will occupy especially reserved seats in the central section of the Ballroom, to which they will be conducted by the Convocation marshal promptly at 8 30. It is customary for all to appear in evening dress.

The Convocation is open to all physicians and their families generally. A cordial invitation is also issued to such of the general public as may be interested.

Following the Convocation Ceremony, the President will present the John Phillips Memorial Medal for 1937-38, and will thereafter deliver the Presidential Address. Dr. Karl T. Compton, President of the Massachusetts Institute of Technology, Cambridge, Mass., will deliver the Convocational Oration, "Possibilities in Biological Engineering."

The Presidential Reception, with dancing, will follow immediately after the program in the Grand Ballroom.

THURSDAY, APRIL 7, 1938

THE ANNUAL BANQUET OF THE COLLEGE will be held in the Grand Ballroom of the Waldorf-Astoria Hotel on Thursday evening at eight o'clock. Dr. James Alexander Miller, General Chairman of the Twenty-second Annual Session of the College, will be the Toastmaster. The address of the evening, "Education in a Changing World," will be delivered by Honorable John H. Finley, LL.D., Associate Editor of the New York Times. Dr. Finley is a well known author and educator, having formerly been Professor of Politics at Princeton University, President of the College of the City of New York and Exchange Harvard Professor to the Sorbonne.

All members of the College, physicians of New York and visitors attending the Session, with their families, are cordially invited. Tickets should be purchased at the Registration Bureau by Wednesday afternoon.

PROGRAM OF ENTERTAINMENT FOR VISITING WOMEN

The Headquarters of the Women's Entertainment Committee will be located in the Empire Room at the Waldorf-Astoria Hotel. Each visitor will receive a program of the activities planned for their entertainment by the Women's Entertainment Committee. A special secretary will be in charge to assist visitors in arranging their entertainment program. Visiting women are requested to register here on arrival and make reservations for the events announced in the program. Additional literature containing information regarding theaters, restaurants, night clubs and other places of entertainment will be available at the registration desk.

The sole purpose of the Women's Entertainment Committee is to assist the visiting women in securing the greatest possible enjoyment and entertainment from their visit to New York. It is hoped that as a result of the activities of this Committee visitors will carry away with them pleasant memories of their stay.

It would greatly facilitate the work of the Committee if each Fellow or Associate who will be attended by ladies will return the card accompanying the program as promptly as possible.

MONDAY, APRIL 4, 1938

Afternoon Registration, Empire Room, Waldorf-Astoria Hotel

Evening 8 15 p m, Reception in Empire Room

9 00 p m, Evening performance at Radio City Music Hall. Feature picture and stage show, including the famous Rockettes.

TUESDAY, APRIL 5, 1938

Morning Free for shopping, etc.

Afternoon 12 30 p m, Luncheon and fashion show in the Empire Room. Tickets, \$2 00.

Evening Theater, optional.

WEDNESDAY, APRIL 6, 1938

Morning Free.

Afternoon 2 30 p m, Visit to the Frick Museum and Metropolitan Museum of Art. Buses leave the Waldorf-Astoria at 2 30 p m. Fare, \$1 00.

5 00 p m, Tea at the Junior League Club House as guests of the Women's Committee.

Evening 8 30 p m, Convocation and dance at the Waldorf-Astoria.

THURSDAY, APRIL 7, 1938

Morning 11 15 a m, Tour of Radio City, including the Museum of Science and Industry, Sky Gardens, Broadcasting Studios, etc. Tickets, \$1 50. Tour ends at 4 00 p m. Luncheon may be had in restaurants in Radio City.

Evening 8 00 p m, Annual Banquet of the College, Waldorf-Astoria.

THE NEW YORK ACADEMY OF MEDICINE at 2 East 103rd Street (on Fifth Avenue) will be open to the members of the American College of Physicians and the participants in its Sessions in New York City.

The Library of the Academy of Medicine is open daily from 9 00 a m to 10 30 p m. The Medical Library is the second largest in the United States, being excelled only by that of the Surgeon General's Library in Washington. The rare books and the Library's incunabula are particularly noteworthy.

The services of the Committee on Medical Education will be available to the members of the American College of Physicians and to all other visiting physicians for information relative to hospitals and clinics throughout the City of New York. The Committee also publishes a daily schedule and bulletin of medical and surgical meetings, lectures, conferences and rounds, as well as a daily list of major surgery in the city's hospitals, open to physicians.

On Friday evening, April 8, at eight-thirty o'clock, Dr. Thomas M. Rivers of the Rockefeller Institute will deliver the Biggs Memorial Lecture at the Academy upon the subject, "The Twentieth Century Version of the De Novo Origin of Infectious Agents, and its Significance in the Control of Disease." All members of the College who remain in New York that evening are cordially invited to attend this meeting.

THE AMERICAN MUSEUM OF NATURAL HISTORY at 77th Street from Columbus Avenue to Central Park West is open every day in the year—week-days, including holidays, from 9 00 a m to 5 00 p m, and Sundays from 1 00 p m to 5 00 p m. There is no charge for admission, excepting to the Planetarium.

The Museum is an institution devoted to the study of the earth and the life existing on it, step by step over a period estimated to be over five hundred million years, from the lowest form to man. Here the fruits of more than half a century of scientific discovery, painstaking research, extensive exploration and courageous pioneering appear in the form of exhibits which reconstruct much of the history of the earth and the mighty animals that once roamed its surface. In the Museum's halls you will find thousands of natural history exhibits from virtually every section of the globe, aside from the special exhibits in the Roosevelt Memorial and the Hayden Planetarium.

THE EXPOSITION AND TECHNICAL EXHIBIT will be located on the Third Floor of the Waldorf-Astoria Hotel.

By official action of the Board of Regents of the College, the Technical Exhibits will be raised to a higher level of excellence through the elimination of all irrelevant and non-scientific entries. The rules adopted, governing this and future Exhibits, are as follows:

- (1) Exhibitors shall be admitted on invitation only,
- (2) The initial approved "Invitation List" shall be made up by the Committee and the Executive Secretary. Both the firm and the product must be approved. Preference shall be given to exhibits of a scientific nature, such as pharmaceuticals, equipment and medical books,
- (3) Additions to the initial approved "Invitation List" may be made by the Committee after application by firms, with the requirement that they submit complete literature concerning their products and their organization,
- (4) The "Invitation List" may be revised annually on the recommendation of the Committee.

The Committee on Exhibits has thoughtfully investigated each exhibit before extending invitations. The number of exhibitors has been reduced, and it is hoped that the members and visiting physicians will find the exhibits more interesting and more beneficial. The exhibits will be particularly representative of the interests of Internal Medicine and its allied specialties, and will include medical literature, pharmaceutical products, apparatus and appliances, specialized physicians' furniture and many other items of special interest. The educational value of these exhibits adds greatly to the interesting features of the meeting. Each doctor is urged to visit each of the booths, for he will certainly find something new and scientifically valuable. Special intermissions in the general program have been arranged, providing additional time for the inspection of exhibits.

LIST OF EXHIBITORS

The following exhibitors have been approved for admission to the Exhibit

| | <i>Space</i> |
|---|--------------|
| Adlanco X-Ray Corporation, New York, N Y | 47-48 |

GENERAL SESSIONS

The object of the General Sessions portion of our program is to provide opportunity for the physicians who constitute our membership, and their guests, to hear statements by competent authorities on topics of lively interest in the fields of internal medicine, the basic sciences, related specialties and other fields in which knowledge gained will better fit the physician to serve the public and practice his profession.

The attempt has been made to provide a diversified and well balanced program. Reports of new and original work are included as well as reviews of important subjects. The desires of the membership as to both topics and speakers have been obtained insofar as this can be done by questionnaire, and heeded in the formation of the program.

In the belief that it is not incumbent upon the physician "to stick to his last" in a meeting of his College, if by that is meant that nothing but purely scientific medicine should be permitted to consider, certain items touching upon *social*, *public* and possibly even *philosophical aspects* of medicine, as well as the more usual ones on diagnosis and treatment, have been included.

GENERAL SESSIONS PROGRAM

Ballroom, Waldorf-Astoria Hotel, New York, N Y

FIRST GENERAL SESSION

Monday Afternoon, April 4, 1938

Presiding Officer

James Alexander Miller, New York, N Y

p m

2 30 Addresses of Welcome

James Alexander Miller, General Chairman of the Twenty-Second Annual Session, and President of the New York Academy of Medicine

Clarence G Bandler, President of the New York County Medical Society

Willard C Rappleye, Dean, College of Physicians and Surgeons, Columbia University

Hon Fiorello H LaGuardia, Mayor of the City of New York

Response to Addresses of Welcome

James H Means, President of the American College of Physicians

OUTLINE OF SESSION

| TIME | MONDAY | TUESDAY | WEDNESDAY | THURSDAY | FRIDAY |
|-----------------------------|--|----------------------------|--|---------------------------|-------------------------------------|
| 9 00 a m to 12 00 m | Morning free Registration, Exhibits, etc | 3d General Session | 4th General Session | 5th General Session | 6th General Session |
| 12 30 p m to 2 00 p m | Luncheon | Round Table Luncheons | Round Table Luncheons | Round Table Luncheons | Round Table Luncheons |
| 2 30 p m to 5 00 p m | 1st General Session | 1st Clinical Session | 2d Clinical Session | 3d Clinical Session | 4th Clinical Session |
| 5 00 p m to 8 00 p m | Dinner | Dinner | Dinner | | 2 30-4 30 4th Lecture Program |
| 8 00 p m to 10 00 p m | 2d General Session followed by Smoker | Open | Convocation, followed by President's Reception | ANNUAL BANQUET | |

- 3 15 Trends in Public Health
Thomas Parran, Surgeon-General, U S Public Health Service, Washington, D C
- 3 45 INTERMISSION
- 4 15 The Social Responsibilities of Medicine
John P Peters, John Slade Ely Professor of Medicine, Yale University School of Medicine, New Haven, Conn (By invitation)
- 4 45 A Broader View of Postmortem Examinations
Alan Gregg, Director for Medical Sciences of the Rockefeller Foundation, New York, N Y (By invitation)
- 5 15 ADJOURNMENT

SECOND GENERAL SESSION

Monday Evening, April 4, 1938

Presiding Officer

William J Kerr, San Francisco, Calif

- p m
- 8 00 The Mechanism of Heat Loss and Temperature Regulation
Eugene F Du Bois, Professor of Medicine, Cornell University Medical College, Medical Director, Russell Sage Institute of Pathology, Physician-in-Chief, New York Hospital, New York, N Y
- 8 20 Some Desirable Supplements to the Present Trends in Medical Investigation
Roger I Lee, Fellow, Harvard University, and Consultant in Internal Medicine, Boston, Mass
- 8 40 Certain Limitations of Preventive Medicine
Henry A Christian, Hersey Professor of the Theory and Practice of Physic, Harvard University Medical School, Physician-in-Chief, Peter Bent Brigham Hospital, Boston, Mass
- 9 00 Clinical and Experimental Observations on Focal Infection
Russell L Cecil, Professor of Clinical Medicine, Cornell University Medical College, New York, N Y, and
D Murray Angevine, Instructor in Pathology, Cornell University Medical College, New York, N Y (By invitation)
- 9 20 The Ageing Process as a Medical-Social Problem
George Morris Piersol, Professor of Medicine, University of Pennsylvania Graduate School of Medicine, Physician-in-Chief, Abington Memorial Hospital, Physician, University of Pennsylvania Graduate Hospital, Philadelphia, Pa, and
Edward L Bortz, Associate Professor of Medicine, University of Pennsylvania Graduate School of Medicine, Chief of Medical Service B, The Lankenau Hospital, Philadelphia, Pa
- 9 40 Nutritional Deficiency Disease
George R Minot, Professor of Medicine, Harvard University Medical School Director, Thorndike Memorial Laboratory, Boston City Hospital, Boston, Mass
- 10 00 ADJOURNMENT

10 20 o'Clock

SMOKER

Ballroom, Waldorf-Astoria Hotel

An interesting and amusing program has been arranged Admission by
registration badge Men only

THIRD GENERAL SESSION

Tuesday Morning, April 5, 1938

Presiding Officer

James E. Paullin, Atlanta, Ga

a m

- 9 00 Experimental Heart Disease
George Edward Hall, Associate Professor, Department of Medical Research, University of Toronto, Toronto, Ont., Canada (By invitation)
- 9 20 Concerning the Association of Bronchial Asthma and Left Ventricular Failure and the Possible Ill Effects from the Use of Epinephrine, unless the Latter can be Excluded
Fred M. Smith, Professor and Head of Department of Theory and Practice of Medicine, State University of Iowa College of Medicine, Physician-in-Chief, University Hospitals, Iowa City, Iowa
- 9 40 Further Comments on Coronary Thrombosis
James B. Herrick, Emeritus Professor of Medicine, Rush Medical College, Chicago, Ill
- 10 00 Obesity and Hypertension Clinical and Experimental Observations
J. Edwin Wood, Jr., Professor of the Practice of Medicine, University of Virginia Department of Medicine, University, Va., and
James R. Cash, Professor of Pathology, University of Virginia Department of Medicine, University, Va. (By invitation)
- 10 15 Climate, Mode of Life, and Heart Disease
Paul D. White, Physician, Massachusetts General Hospital, Lecturer in Medicine, Harvard University Medical School, Boston, Mass
- 10 30 INTERMISSION
- 11 00 Physiologic Effects of Operation (Bilateral Resection of Splanchnic Nerves and First and Second Lumbar Ganglia) for Essential Hypertension
Edgar V. Allen, Associate Professor of Medicine, University of Minnesota (Mayo Foundation), Head of Section in Division of Medicine, Mayo Clinic, Rochester, Minn., and
A. W. Adson, Professor of Neurosurgery, University of Minnesota (Mayo Foundation), Head of Section on Neurosurgery, Mayo Clinic, Rochester, Minn. (By invitation)
- 11 20 Prophylaxis in Allergy
Richard A. Kern, Professor of Clinical Medicine, University of Pennsylvania School of Medicine and Graduate School of Medicine, Chief of Allergy Section and Chief of Outpatient Department, Hospital of the University of Pennsylvania, Philadelphia, Pa

- 11 40 Physiological Methods in the Diagnosis and Treatment of Asthma and Emphysema (Moving Picture Demonstration)
 Alan L. Barach, Assistant Professor of Clinical Medicine, Columbia University College of Physicians and Surgeons, New York, N. Y.
- 12 00 ADJOURNMENT

FOURTH GENERAL SESSION

Wednesday Morning, April 6, 1938

Presiding Officer

G. Gill Richards, Salt Lake City, Utah

- a m
- 9 00 Chronic Brucellosis (Undulant Fever) An Analytical Study of the Positive Reactors among School Children
 Fred E. Angle and William H. Algie, Department of Medicine, University of Kansas Hospitals, Attending Physicians to Bethany Methodist Hospital, Providence Hospital and St. Margaret's Hospital, Kansas City, Kan.
- 9 15 Prognosis and Treatment of Erysipelas
 John A. Toomey, Associate Professor of Pediatrics, Western Reserve University School of Medicine, Cleveland, Ohio
- 9 35 The Value of Antitoxin in Scarlet Fever
 Francis G. Blake, Sterling Professor of Medicine, Yale University School of Medicine, Physician-in-Chief, New Haven Hospital, New Haven, Conn.
- 9 50 Factors Influencing the Incidence and Course of Otitis Media in Scarlet Fever
 Conrad Wesselhoef, Associate Professor of Theory and Practice, Boston University School of Medicine, Associate in Communicable Diseases (Department of Pediatrics and School of Public Health), Harvard University Medical School, Boston, Mass.
- 10 10 The Present Status of Methods for the Prophylaxis of Acute Anterior Polymyelitis
 John A. Kolmer, Professor of Medicine, Temple University School of Medicine, Director of the Research Institute of Cutaneous Medicine, Philadelphia, Pa.
- 10 30 INTERMISSION
- 11 00 Observations on the Clinical Aspects, Complications and Treatment of Acute Upper Respiratory Tract Infections
 Arlie V. Bock, Henry K. Oliver Professor of Hygiene, Harvard University, Physician, Massachusetts General Hospital, Boston, Mass. (By invitation)
- 11 15 The Affective Disorders in Medical Practice
 Thomas P. Sprunt, Associate in Medicine, Johns Hopkins University School of Medicine, Associate Professor of Medicine, University of Maryland School of Medicine, Baltimore, Md.
- 11 30 Experimental Observations on the Treatment of Hypertension
 Harry Goldblatt, Professor of Experimental Pathology and Associate Director of the Institute of Pathology, Western Reserve University School of Medicine, Cleveland, Ohio (By invitation)

- 11 50 Experiences with Insulins of Prolonged Activity in Ambulatory Patients
 H Clare Shepardson, Associate Clinical Professor of Medicine, University of California Medical School, San Francisco, Calif, and
 Richard D Friedlander, Instructor in Medicine, University of California Medical School, San Francisco, Calif (By invitation)
- 12 00 ADJOURNMENT

ANNUAL CONVOCATION

Wednesday Evening, April 6, 1938

8 30 o'Clock

Grand Ballroom, Waldorf-Astoria Hotel

All members of the profession and the general public are cordially invited No special admission tickets will be required

- 1 Address by the President of the College
 James Howard Means
- 2 Presentation of newly-elected Fellows and recital of the Pledge
 George Morris Piersol, *Secretary General*
- 3 Presentation of John Phillips Memorial Medal for 1937-38
- 4 Announcement of Research Fellow of the College for 1938
- 5 Convocational Oration "Possibilities in Biological Engineering"
 Karl T Compton, President, Massachusetts Institute of Technology, Cambridge, Mass

President's Reception

The Reception and Dance will follow immediately after the program Newly-inducted Fellows should sign the Roster and secure their Fellowship Certificates during the Reception

FIFTH GENERAL SESSION

Thursday Morning, April 7, 1938

Presiding Officer

William D Stroud, Philadelphia, Pa

a m

- 9 00 The Clinical Significance of Punctate Basophilia in the Erythrocyte
 Ernest H Falconer, Clinical Professor of Medicine, University of California Medical School, San Francisco, Calif
- 9 15 Macrocytic Anemias, other than Pernicious Anemia, Associated with Lesions of the Gastrointestinal Tract
 Cyrus C Sturgis, Professor of Internal Medicine, University of Michigan Medical School, Director, Thomas Henry Simpson Memorial Institute for Medical Research, Director, Department of Internal Medicine, University Hospital, Ann Arbor, Mich
- 9 35 Clinical and Hematological Review of Sprue based on the Study of 150 Cases
 Ramon M Suárez, Associate Clinical Professor of Tropical Medicine, School of Tropical Medicine of Puerto Rico, San Juan, P R

- 9 55 The Challenge of Appendicitis
Reginald Fitz, Wade Professor of Medicine, Boston University School of
Medicine, Director, Evans Memorial, Boston, Mass
- 10 15 Correlation of Clinical and Laboratory Data in Diseases of Lymph Nodes
Raphael Isaacs, Associate Professor of Medicine, University of Michigan
Medical School, Assistant Director, Thomas Henry Simpson Mem-
orial Institute for Medical Research, Ann Arbor, Mich
- 10 30 INTERMISSION
- 11 00 Concerning the Acquired Resistance of Fixed Tissue Cells to Injury
(Lantern slides)
William de B MacNider, Kenan Research Professor of Pharmacology,
and Dean University of North Carolina School of Medicine, Chapel
Hill, N C
- 11 30 ADJOURNMENT, to be followed by

ANNUAL BUSINESS MEETING

The Annual Business Meeting of the College will be held immediately after the last paper. All Masters and Fellows are urged to be present. An amendment to the By-Laws of the College is to be presented for consideration and adoption. Official reports from the Treasurer and Executive Secretary will be read, new Officers, Regents and Governors will be elected, and the President-Elect, Dr William J Kerr, will be inducted into office.

Thursday Evening, 8 00 o'Clock

Ballroom, Waldorf-Astoria Hotel

THE ANNUAL BANQUET OF THE COLLEGE

(Procure Tickets at the Registration Bureau)

Consult Special Banquet Program

Toastmaster James Alexander Miller, New York, N Y

Address of the Evening "Education in a Changing World" Hon John H Finley,
LL D, Associate Editor of the New York Times

SIXTH GENERAL SESSION

Friday Morning, April 8, 1938

Presiding Officer

James D Bruce, Ann Arbor, Mich

a m

- 9 00 A Differential Classification of the Various Types of Colitis Their Manage-
ment

J Arnold Bargen, Associate Professor of Medicine, University of Min-
nesota (Mayo Foundation), Consultant in Medicine, Mayo Clinic,
Rochester, Minn

- 9 15 Hypoglycemia Following Encephalitis

Jonathan C Meakins, Professor of Medicine and Director of Department,
McGill University Faculty of Medicine, Physician-in-Chief, Royal
Victoria Hospital, Montreal, Que, Canada

- 9 30 Basal Metabolism The Practical Significance of the "Variability" as Distinguished from the "Constancy" of the Basal Metabolic Rate in Individuals and in Various Groups of Diseases
Walter M Boothby, Professor of Experimental Metabolism, University of Minnesota (Mayo Foundation), Head of Section for Metabolic Investigation, Mayo Clinic, Rochester, Minn
- 9 50 Studies on the Pathologic Physiology of the Exophthalmos of Graves' Disease
David Marine, Assistant Professor of Pathology, Columbia University College of Physicians and Surgeons, Director of Laboratories, Montefiore Hospital, New York, N Y
- 10 10 Experiences in Treating Exophthalmic Goiter in a Large Municipal Hospital
Willard O Thompson, Associate Clinical Professor of Medicine, Rush Medical College, Research Associate in Pathology, Cook County Hospital, Chicago, Ill ,
S G Taylor, III, Clinical Associate in Medicine, Rush Medical College, Chicago, Ill (By invitation),
Karl A Meyer, Associate Professor of Surgery, Northwestern University Medical School, Attending Surgeon and Medical Superintendent, Cook County Hospital, Chicago, Ill (By invitation),
R W McNealy, Associate Professor of Surgery, Northwestern University Medical School, Attending Surgeon, Cook County Hospital, Chicago, Ill (By invitation)
- 10 30 INTERMISSION
- 11 00 Cevitamic Acid A Critical Analysis of Its Use in Clinical Medicine
Irving S Wright, Assistant Professor of Clinical Medicine, Columbia University, New York, N Y
- 11 20 Common Gastrointestinal Emergencies Their Early Recognition and Treatment
George B Eusterman, Professor of Medicine, University of Minnesota (Mayo Foundation), Head of Section on Medicine, Mayo Clinic, Rochester, Minn
- 11 40 Acute Disseminated Lupus Erythematosus—a Systemic Disease
Edward Rose, Assistant Professor of Clinical Medicine, University of Pennsylvania School of Medicine, Philadelphia, Pa , and
Donald M Pillsbury, Assistant Professor of Dermatology and Syphilology, University of Pennsylvania School of Medicine, Philadelphia, Pa (By invitation)
- 12 00 ADJOURNMENT

PROGRAM OF AFTERNOON LECTURES

This course of Afternoon Lectures is a feature of the program arranged at the request of a large number of members. The course is presented as an elective, as a whole or for individual days, in place of hospital clinics. The lectures will not conflict with the General Sessions or with the Round Table Luncheon-Conferences. The lectures will be presented daily, Tuesday to Friday, inclusive, from 2 30 to 4 30 p m , in the Ballroom of the Waldorf-Astoria Hotel.

This year the attempt has been made to devote most of the lectures to problems in therapeutics. The newer drugs such as sulphanilamide, physical therapy, oxygen therapy and psychotherapy will be presented, and also papers on treatment of disturbances of sodium metabolism and of such diseases as hypertension and disorders of the liver.

The lectures will be open to all members and guests of the College.
Admission by regular registration badge

Tuesday Afternoon, April 5, 1938

BALLROOM, WALDORF-ASTORIA HOTEL

Presiding Officer

Chauncey Warring Dowden, Louisville, Ky

p m

- 2 30 Therapeutics of Liver Disease
Albert M Snell, Associate Professor of Medicine, University of Minnesota (Mayo Foundation), Head of a Section on Medicine, Mayo Clinic, Rochester, Minn, and
Jesse L Bollman, Associate Professor of Experimental Pathology, University of Minnesota (Mayo Foundation), Associate in Division of Experimental Surgery and Pathology, Mayo Clinic, Rochester, Minn (By invitation)
- 3 30 Recent Advances in the Use of Drugs for Treatment of Bacterial Infections
Eli Kennerly Marshall, Jr, Professor of Pharmacology and Experimental Therapeutics, The Johns Hopkins University School of Medicine, Baltimore, Md (By invitation)

PROGRAM OF ROUND TABLES

Tuesday, April 5, 1938

WALDORF-ASTORIA HOTEL

Le Perroquet Suite, Fourth Floor

(Capacity, 150)

I

12 30-2 00 p m ROUND TABLE on Diabetes Mellitus

Leader Russell M Wilder, Professor and Chief of Department of Medicine,
University of Minnesota (Mayo Foundation), Consulting Physician, Mayo
Clinic, Rochester, Minn

 WALDORF-ASTORIA HOTEL

Jansen Suite Dining Room, Fourth Floor

(Capacity, 75)

II

12 30-2 00 p m ROUND TABLE on Syphilis

Leader Thomas Parran, Surgeon-General, United States Public Health
Service, Washington, D C

 WALDORF-ASTORIA HOTEL

Jansen Suite Salon, Fourth Floor

(Capacity, 100)

III

12 30-2 00 p m ROUND TABLE on Tuberculosis

Leader Gerald B Webb, Consulting Physician, Sunnyrest Sanatorium,
Glockner Sanatorium and Hospital, National Methodist Episcopal Sana-
torium for Tuberculosis and St Francis Hospital and Sanatorium,
President, Colorado Foundation for Research in Tuberculosis, Colorado
Springs, Colo

 WALDORF-ASTORIA HOTEL

Assembly Rooms M to R, Fourth Floor

(Capacity, 100)

IV

12 30-2 00 p m ROUND TABLE on Gastro-Enterology

Leader T Grier Miller, Professor of Clinical Medicine, University of Penn-
sylvania School of Medicine, Chief of Gastrointestinal Section, Hospital
of the University of Pennsylvania, Philadelphia, Pa

WALDORF-ASTORIA HOTEL

West Foyer, Third Floor

(Capacity, 200)

V

12 30-2 00 p m ROUND TABLE on Cardiology

Leader Paul D White, Physician, Massachusetts General Hospital, Lecturer
in Medicine, Harvard University Medical School, Boston, Mass

Wednesday, April 6, 1938

WALDORF-ASTORIA HOTEL

Le Perioquet Suite, Fourth Floor

(Capacity, 150)

VI

12 30-2 00 p m ROUND TABLE on Diseases of Allergy

Leader Robert A Cooke, Assistant Professor of Clinical Medicine, Cornell
University Medical College, Special Consultant in Allergy and Director
of Department of Allergy, Roosevelt Hospital, New York, N Y

WALDORF-ASTORIA HOTEL

Jansen Suite Dining Room, Fourth Floor

(Capacity, 75)

VII

12 30-2 00 p m ROUND TABLE on Vascular Disease

Leader Eugene M Landis, Assistant Professor of Medicine and Research
Associate in Pharmacology, University of Pennsylvania School of Medi-
cine, Philadelphia, Pa

WALDORF-ASTORIA HOTEL

Jansen Suite Salon, Fourth Floor

(Capacity, 100)

VIII

12 30-2 00 p m ROUND TABLE on Disorders of Nutrition

Leader William P Murphy, Associate in Medicine, Harvard University Medi-
cal School, Senior Associate in Medicine, Peter Bent Brigham Hospital,
Boston, Mass

WALDORF-ASTORIA HOTEL

Assembly Rooms M to R, Fourth Floor

(Capacity, 100)

IX

12 30-2 00 p m ROUND TABLE on Psychoneuroses

Leader Austen Fox Riggs, Clinical Professor of Neurology, Columbia Uni-

versity College of Physicians and Surgeons, Medical Director and President of Austen Riggs Foundation, Stockbridge, Mass

WALDORF-ASTORIA HOTEL

West Foyer, Third Floor

(Capacity, 200)

X

12 30-2 00 p m ROUND TABLE on Endocrinology

Leader David P Barr, Professor of Medicine, Washington University School of Medicine, Physician-in-Chief, Barnes Hospital, St Louis, Mo

Thursday, April 7, 1938

WALDORF-ASTORIA HOTEL

Le Perroquet Suite, Fourth Floor

(Capacity, 150)

XI

12 30-2 00 p m ROUND TABLE on Pneumonia

Leader Russell L Cecil, Professor of Clinical Medicine, Cornell University Medical College, Associate Visiting Physician, New York Hospital, New York, N Y

WALDORF-ASTORIA HOTEL

Jansen Suite Dining Room, Fourth Floor

(Capacity, 75)

XII

12 30-2 00 p m ROUND TABLE on Arthritis

Leader Ralph H Boots, Associate in Medicine, Columbia University College of Physicians and Surgeons, Assistant Attending Physician and Physician to Arthritis Clinic, Presbyterian Hospital, New York, N Y

WALDORF-ASTORIA HOTEL

Jansen Suite Salon, Fourth Floor

(Capacity, 100)

XIII

12 30-2 00 p m ROUND TABLE on Cardiology

Leader Robert L Levy, Professor of Clinical Medicine, Columbia University College of Physicians and Surgeons, Associate Visiting Physician and Cardiologist, Presbyterian Hospital, New York, N Y

WALDORF-ASTORIA HOTEL

Assembly Rooms M to R, Fourth Floor

(Capacity, 100)

XIV

12 30-2 00 p m ROUND TABLE on Diabetes Mellitus

Leader H O Mosenthal, Professor of Medicine, New York Post-Graduate Medical School, Columbia University, Attending Physician, New York Post-Graduate Hospital, New York, N Y

WALDORF-ASTORIA HOTEL

West Foyer, Third Floor

(Capacity, 200)

XV

12 30-2 00 p m ROUND TABLE on Diseases of the Blood

Leader George R Minot, Professor of Medicine, Harvard University Medical School, Director, Thorndike Memorial Laboratory, Boston City Hospital, Boston, Mass

Friday, April 8, 1938

WALDORF-ASTORIA HOTEL

Le Perroquet Suite, Fourth Floor

(Capacity, 150)

XVI

12 30-2 00 p m ROUND TABLE on Diseases of Allergy

Leader Francis M Rackemann, Associate in Medicine, Harvard University Medical School, Physician and Chief of Medical Department, Massachusetts General Hospital, Boston, Mass

WALDORF-ASTORIA HOTEL

Jansen Suite Dining Room, Fourth Floor

(Capacity, 75)

XVII

12 30-2 00 p m ROUND TABLE on Tuberculosis

Leader J Burns Amberson, Jr, Professor of Clinical Medicine, Columbia University College of Physicians and Surgeons and New York University College of Medicine, Visiting Physician, Tuberculosis Service, Bellevue Hospital, New York, N Y

WALDORF-ASTORIA HOTEL

Jansen Suite Salon, Fourth Floor

(Capacity, 100)

XVIII

12 30-2 00 p m ROUND TABLE on Gastro-enterology

Leader George B Eusterman, Professor of Medicine, University of Minnesota (Mayo Foundation), Head of Section on Medicine, Mayo Clinic, Rochester, Minn

WALDORF-ASTORIA HOTEL

Assembly Rooms M to R, Fourth Floor

(Capacity, 100)

WALDORF-ASTORIA HOTEL

West Foyer, Third Floor

(Capacity, 200)

XX

12 30-2 00 p m ROUND TABLE on Virus Diseases

Leader Thomas Francis, Jr, Member of the Staff of the International Health Division of the Rockefeller Foundation, New York, N Y

PROGRAM OF CLINICS AND SPECIAL DEMONSTRATIONS

The Program for the Clinical Sessions has been completed, and, following an old New York custom, clinics will be held in the afternoon instead of in the morning

There will be three separate clinics on each of the four days at Bellevue, New York and Presbyterian Hospitals At Mount Sinai there will be two programs each day The Department of Health is giving one clinic on each of the four days The Hospital of the Rockefeller Institute is giving two programs during the week and the following hospitals are each offering one program on one afternoon Roosevelt, St Luke's, Long Island College and Post-Graduate

All these clinics are to be patient-clinics, not lectures, and special effort has been made to have each clinic a sort of symposium dealing with the clinical phases of some one particular branch of medicine such as cardiac, vitamin, endocrine, renal or blood diseases As a matter of fact, all the fields of medicine seem to be fairly well covered in the programs outlined

Stress has also been laid on the Clinical Pathological Conferences and one or more of these will be found on each of the afternoons Some of the clinics belong

in the group of general medicine in which the run-of-the-ward cases will be presented and discussed by the attending staff. This makes it possible to do away with the ward walks which had to be limited to very small groups.

The clinics to be given by the Department of Health draw the material from their very large clinics on syphilis and gonorrhea and deal with these important subjects, not only from the standpoint of diagnosis and therapy, but also from their public health and preventive aspects.

Of course, it has not been possible to utilize all of the vast facilities that New York affords nor to avail ourselves of the opportunities that were offered by many of the other hospitals and institutions in the city. It did not seem wise to provide seating capacity in excess of that demanded by the College for such sessions, the clinics as offered will accommodate 2,500 individuals daily.

Clinic Sessions will begin promptly at 2:30 o'clock in the afternoon. *Everyone who wishes to attend a clinic must secure a ticket, for the collection of tickets will be rigidly enforced.*

There will also be a few special demonstrations for relatively small groups. Those who are interested will have an opportunity to see Dr. Barach's oxygen and helium apparatus in practical use at the Presbyterian Hospital where Dr. Francis Carter Wood will also demonstrate the high voltage (1,000,000 volts) x-ray machine recently installed in the hospital.

At Mount Sinai Hospital Dr. Robert Frank will demonstrate his method of assaying sex hormones, and Dr. Reuben Ottenberg and his associates will demonstrate technical methods for studying liver function.

At Bellevue Dr. Howard Fox will have a small clinic for the demonstration of some especially interesting cases of cutaneous syphilis and Dr. Lucy Sutton will exhibit apparatus for fever therapy in children.

At New York Hospital Dr. Henry Richardson and his associates will give a special demonstration on various aspects of bronchiectasis and Dr. Eugene Du Bois will show his new metabolism unit for research purposes.

It will be noted that many of these demonstrations occupy only a relatively small portion of the time allotted to clinic sessions in an afternoon. It has been arranged that Fellows desiring to attend these short demonstrations may attend any of the other clinics that are in progress at the same hospital during the remainder of the afternoon, either before or after the demonstration. In this way they will not sacrifice an entire afternoon for a relatively short demonstration.

The Committee responsible for the assembling of these clinics has received the cordial cooperation of the staffs in the hospitals contributing and trusts that the program will meet with the hearty approval of the Fellows of the College.

NEW YORK CITY AS A MEDICAL CENTER

HISTORICAL RETROSPECT

DR JAMES J WALSH, author of "The History of Medicine in New York State," is authority for the statement that the history of medicine began when the first permanent colonists located at Fort Orange in 1625. There arrived two "consolers of the sick," Bastiaen Jansen Crol and Jan Huyck, who also conducted religious services until the arrival of the first ordained minister in 1628. In 1633 a second minister arrived, accompanied by a schoolmaster. Both added to the medical resources, for it was the duty of the schoolmaster to assist the dominie as consoler of the sick as well as to serve as the teacher of youth.

Any retrospect of medicine in New York would require frequent references to the contributions made to the subject by Dr Walsh, and fortunately we have been allowed the liberty, by that distinguished physician and author, of quoting freely from his works in this brief presentation.

"The first surgeon (chirurgion) to settle in the province of New York," writes Dr Walsh, "was Harmen Meyndertsen Van den Bogaert, who arrived in New Amsterdam in 1631, as the surgeon of the ship 'Eendracht'. He became surgeon to Fort Orange (now Albany), and was noted for his cordial relations with the Indians, but was a victim to their treachery. O'Callaghan, in his History of New Netherlands, gives the name of an English surgeon, William Beaton (chirurgion to the ship 'William,' of London) who practiced in New Amsterdam. The landing of ship surgeons led the Council of New Amsterdam to request Dr Johannes La Montagne to issue permits to those sufficiently expert in medicine and surgery to practice in the colony. He also had the additional duty of determining the fitness of the barber surgeons who wanted to practice here. Toner notes the jealousy among the barber surgeons, as well as their frequent lack of skill, and the constant necessity for legal regulation. Dr La Montagne, a Huguenot from Holland in 1637, was the first regular graduate in medicine to practice in the province, having received his degree from the University of Leyden. He acted as schoolmaster as well as physician, had a seat in the Council, and was vice director in command of Fort Orange. Kiliaen Van Rensselaer in 1642 engaged Abraham Staes to go to the colony as surgeon.

"The first medical book to be published in what is now the United States was Dr John Jones's "Plan, Concise and Practical Remarks on the Treatment of Wounds and Fractures." The author was the surgeon-general of the Continental troops. Mumford, in his Surgical Memoirs, said

' American surgeons must look back to John Jones of New York as the first of their eminent professional forebears ' Dr Jones was a medical apprentice of Dr Cadwalader, of Philadelphia, the best-known surgeon in the country at that time Thence Jones went to London, to come under the influence of John Hunter and Percival Pott, and to Paris to study under Petit and Le Dran, considered the greatest surgical teachers of the time After a period at Edinburgh under Monro, he returned to America to become surgeon to the American troops in the French and Indian War When he volunteered his services to the colonies during the Revolution, he was appointed surgeon-general and proved just the man for the position The Continentals had the advantage of the best surgery of the time Cadwalader Colden was an eminent physician, who devoted more time to science, government and history than to medicine

" The colonies generally were infested by quacks and medical charlatans, and newspapers were used to advertise their curealls In 1753, a medical regulation act was passed which required that ' all the physicians, surgeons and apothecaries in the province are to be licensed by a board consisting of the four oldest members of his Majesty's Council, the judges of the Supreme Court, the representatives of the City and Assembly, our Mayor and Recorder for the time being, or any seven of them, with the assistance of two physicians and two surgeons by the majority of them elected Until after examination and licensing no one shall practice Examinations shall be public '

" No bills for medical services were collectable unless the practitioner had a license There were already complaints as to exorbitance of doctors' fees, so the bills of physicians were to be submitted to an examiner appointed for that purpose, before presentation to the patient It has been estimated by Toner that at the time of the Revolution there were 3,500 physicians in the colonies, of whom only 400 held the degree of M D A list of thirty-five has been compiled for New York alone

" New York was a pioneer in American medical education According to Dr David Hosack, the founder of the botanical gardens on the site of which Rockefeller Center has been built, the first effort at the formal teaching of medicine in this country was the private course in human anatomy offered in New York City by Dr John Bard and Dr Peter Middleton, probably before 1750 The first formal teaching of anatomy in this country, in connection with an organized educational institution, was a course of lectures given at King's College, now Columbia University, in 1763 by Dr Samuel Clossey, a graduate of Trinity College, Dublin Five years later, Dr Peter Middleton and Dr Samuel Bard, the son of Dr John Bard, the first physician to practice dissection in America, established the medical department of King's College This institution gave the first degree of Bachelor of Medicine in 1769 The first degree of Doctor of Medicine was bestowed in New York in 1770 on Robert Tucker, and the second in

1771 on Samuel Kissam Dr Samuel Bard, professor of the theory and practice of physics in New York, Mumford declares to have been the most eminent physician of his time with the single exception of Dr Rush

"During the Revolution, medical instruction was irregular After the Revolution the Columbia school resumed its classes and suffered severely from the 'Doctors' Riot' which took place in 1788, because of popular opposition to dissection No legal way of obtaining bodies for purposes of dissection existed Resurrectionism, that is the surreptitious removal of the recently buried to the dissecting room, was a common practice On Sunday, April 13, 1788, some boys saw a dissected arm hanging in a window of the medical school, and when they called attention to it, a crowd collected Some of them forcibly entered the building and destroyed many anatomical preparations On Monday morning, a crowd collected around the college, and the mayor attempted to soothe their feelings In the afternoon, the crowd gathered around the jail in which the doctors and medical students had taken refuge because of threatened violence Baron Steuben, of Revolutionary fame, tried to pacify the mob They knocked him down, and so upset his dignity that he quite lost his temper, calling out to the mayor, 'Fire! Duane, fire!' and the militia, summoned for protection, fired, killing seven rioters and wounding many more After this the mob dispersed

"The New York riot led to the passage of a law, in 1789, that 'science might not be injured by preventing the dissection of proper subjects' This law provided that 'when any offender shall be convicted of murder, arson or burglary for which he shall be sentenced to suffer death, the courts may at their discretion add to the judgment that the body of such offender shall be delivered to the surgeons for dissection' This legal provision of the bodies of executed criminals proved utterly inadequate for teaching by dissection, and 'body snatching' continued

"It was more than sixty years after the 'Doctors' Riot,' before a law (1854) was enacted by the New York legislature, granting unclaimed bodies for anatomical purposes Many prominent physicians recalled, later in life, unearthing bodies from cemeteries on Long Island, when they were students, and smuggling them across the ferry Dr Hartwell, in his lecture on 'The Hindrances to Anatomical Study in the United States, Including a Special Record of the Struggles of Our Early Anatomical Teachers,' tells of incidents similar to the Doctors' Riot in other cities

"The Medical School of Columbia College was united in 1814 with the College of Physicians and Surgeons in the City of New York which had been incorporated in 1807 Not for a number of years were these pioneer medical schools followed by others—the New York Medical College (1850), the short-lived Metropolitan Medical College (1857–62), the Homeopathic Medical College (1860), the Bellevue Hospital Medical College (1861), and the Eclectic Medical College (1865)

"The first medical college in the state outside of the metropolis was the College of Physicians and Surgeons of the Western District of the State of New York, established at Fairfield, in 1809. After incorporation in 1812, this College continued to function until 1840, having graduated 609 physicians. Geneva Medical College, established in 1835, and Albany Medical College, incorporated in 1838, continued to advance medical education. The number of medical colleges increased, until in 1882 there were 13, with 2,982 students, and property valued at more than \$703,000. The first woman in the United States to receive the degree of Doctor of Medicine was Elizabeth Blackwell, who graduated from the Geneva Medical College in 1849. Fifteen years later, the New York Medical College for Women was incorporated, to be followed in 1866 by the Women's College of Physicians and Surgeons. At the present time (1936), there are in the state 9 medical colleges with 2,507 students enrolled.

"New York's priority in this country in the provision of postgraduate education for physicians is worth noting. Struggling practitioners of medicine who had received very limited medical education and were sincerely desirous of doing better professional work, could take several months from their practice and spend these at postgraduate study, to the decided advantage of themselves and their patients. The first of these graduate medical schools was the New York Polyclinic, founded in 1882 by Dr. John Allen Wyeth, himself a distinguished surgeon, one of the many progressive workers in surgery whom New York owes to the South. He had served with distinction in the Confederate army, and was looked upon as a leader in the profession. He is honored by a statue to him on the grounds of the capitol of Montgomery, Alabama, his native state. The postgraduate work in medicine that he initiated was taken up in other cities throughout the country and came to be a valued feature of American medical teaching.

"Dr. Valentine Seaman, at New York Hospital, was the pioneer in this country in the training of nurses. The inscription below his portrait in the hospital commemorates this: 'In 1798 he organized in the New York Hospital the first regular training school for nurses, from which other schools have since been established and extended their blessings throughout the country.' In 1872, Bellevue Hospital secured Nightingale nurses and thus introduced the modern trained nurse into America. Up to this time, the nurses at Bellevue were mainly women who had been sentenced to the workhouse, which constituted one part of Bellevue under the commissioner of charities and correction. After sobering up, they were transferred to the hospital as nurses, if they had had any experience in family nursing. When the Nightingale nurses came from London, these women stoned them and called them 'scabs' and 'blacklegs,' imported from England to take the jobs of good Americans.

"Bellevue was about as insanitary as a hospital could possibly be. Its death rate was extremely high. Infection was always rife. Erysipelas

FIG 1 Bellevue Hospital (By permission of the New York Daily News)

often proved fatal to surgical patients. No wonder the poor dreaded the hospital, though this was true of hospitals everywhere. It was almost worse to go to a hospital than to the poorhouse. Pasteur's discoveries in bacteriology, applied by Lister to surgery, reformed hospitals, though not until well toward the end of the nineteenth century. The trained nurse proved a valuable factor in this consummation so urgently needed."

MEDICINE IN NEW YORK TODAY

New York City's opportunities for medical education are extensive. In all, there are 183 hospitals approved by the American Medical Association, with 837 approved internships available annually, and offering 396 annually available approved "residencies." Fifteen institutions offer post-graduate instruction.

Five medical schools are located in New York City: Columbia University College of Physicians and Surgeons, Cornell University Medical College, Long Island College of Medicine, New York Homeopathic College and Hospital, and New York University College of Medicine.

New York City is divided into five counties by boroughs: New York, Kings (Brooklyn), Queens, Bronx and Richmond (Staten Island). In each of these there is a county medical society which is an integral part of the Medical Society of the State of New York and the American Medical Association. Their membership comprises: New York, 4,755, Kings, 2,645, Queens, 809, Bronx, 1,247, and Richmond, 122.

The New York Academy of Medicine, at 2 East 103rd Street, Manhattan, was organized in 1847 and exists to advance medical knowledge. Its library is the second largest in the United States, containing 224,000 volumes. In Brooklyn, the Medical Society of the County of Kings has affiliated with it an Academy of Medicine at 1313 Bedford Avenue, Brooklyn, with a medical library ranking fourth in size in the country, containing 143,000 volumes. Both libraries contain many thousands of pamphlets and current medical journals available for reference.

During the course of the annual session, clinics and demonstrations will be held in the following hospitals: Bellevue, New York Hospital, Long Island College Hospital, St. Luke's, Roosevelt, Mt. Sinai, Presbyterian, and Post-Graduate Medical School and Hospital, also at the Rockefeller Institute for Medical Research and the Department of Health of New York City.

Bellevue Hospital—Bellevue Hospital is located at the foot of East 26th Street. It is the oldest hospital in the United States. Established in 1736, it was then known as the "Almshouse." In 1844 the teaching of medical students was begun and now the facilities of the hospital are utilized for teaching purposes by New York University, The College of Physicians and

Surgeons, Columbia University and by Cornell University Medical College. The Medical and Surgical Divisions are under the supervision of the Commissioner of Hospitals. The Training School for Nurses was opened in 1873. In 1887 a Training School for Male Nurses was begun. The present bed capacity is 2,431 and during 1938 the new Chest Building will be opened, adding an additional 360 beds. The hospital maintains a large Out-Patient Department and 612,378 patients' visits were cared for during the year 1937. The staff consists of a medical superintendent and assistant superintendents, 550 visiting physicians, 28 resident physicians, 198 interns and more than 1,000 nurses.

FIG 2 New York Hospital—Cornell Medical Center

New York Hospital (York Avenue and 68th Street) The Society of the New York Hospital was chartered in 1771 during the reign of George III, and during the Revolutionary War the hospital was used by the British. Since that time it has been a teaching hospital, and from 1912 its principal teaching affiliation has been with Cornell University Medical College. In 1932 the following institutions moved into the same group of buildings:

Society of the New York Hospital, Society of the Lying-In Hospital of the City of New York, Manhattan Maternity and Dispensary, New York Nursery and Child's Hospital, and Cornell University Medical College. The "New York Hospital—Cornell Medical College Association" is an informal committee which serves as a medium for coordinating the joint activities of the two institutions. Ground was broken for the Medical Center in 1929. The cost of the Center was approximately \$15,000,000. The main building is twenty-six stories high.

Long Island College Hospital (Henry and Pacific Streets, Brooklyn). Founded in 1858, this was the first medical college in the United States to incorporate its own hospital.

FIG 3 Long Island College Hospital

The first course of lectures at the Medical School began on March 30, 1860. In this same year the number of hospital beds was increased to provide for the many sick and wounded soldiers of the Civil War. The Long Island College Hospital was the first hospital in the Metropolitan District to receive wounded soldiers for nursing and medical treatment. The Long Island College Hospital has grown from an infant institution of twenty-five beds, housed in a private dwelling, to a modern hospital of 486 beds, a modern laboratory, a nurses home and a clinic treating 123,819

FIG 4 St Luke's Hospital

patients a year. In 1930 the college and the hospital separated, the college changing its name to the Long Island College of Medicine. It still uses the hospital freely in teaching. The present hospital building is about thirty years old, while the Polhemus Memorial Clinic was built in 1896. The Hoagland Laboratory (1887), which was the first bacteriological laboratory built in the United States, and the Polak Laboratory (1931), are included in the group of buildings about the college.

St Luke's Hospital (Cathedral Heights, 113th Street and Amsterdam Avenue) The hospital is open at all times for medical and surgical aid and nursing to the sick, and disabled from acute, curable, non-contagious

FIG 5 Roosevelt Hospital

diseases, without distinction of race or color. Cases demanding immediate care are received at any hour of the day or night. The hospital is supported by voluntary contributions and endowments. It is free to those unable to pay for services. St. Luke's also maintains a dispensary, training school for nurses and a hospital service.

Roosevelt Hospital (Ninth Avenue and 59th Street) Roosevelt Hospital was opened in 1871. It is a general hospital with 391 beds. In 1936

FIG 6 Mt Sinai Hospital

there were 7 351 patients admitted and 66 085 visits were made to the Out-Patient Department. It is used for clinical teaching by the College of Physicians and Surgeons of Columbia University. A training school for nurses and an emergency department are conducted by the institution.

Mt Sinai Hospital (Fifth and Madison Avenues between 100th and 101st Streets). Organized in 1852 for "benevolent, charitable and scientific purposes." The work of the hospital was begun in a small private dwelling on 28th Street between 7th and 8th Avenues. It accommodated 28 patients. The hospital now has accommodations for 856 patients, including eighteen beds in the Receiving Ward, 250,000 visits are made annually to its Out-Patient Clinic. Mt Sinai created a precedent among the hospitals in New York in 1878 by setting up a distinct pediatric service, and

FIG 7 Columbia-Presbyterian Medical Center

an otological service in 1879. There is a training school for nurses in connection with Mt Sinai, which was incorporated in 1881. The present hospital was completed and occupied March 15, 1904. Additions to the original group of buildings have been made continuously since that time. The Research Foundation of the Mt Sinai Hospital was incorporated in 1936, "to conduct, promote, encourage and assist investigation in the services and arts of hygiene, medicine, surgery and allied subjects."

Presbyterian Hospital. Located with twelve other units composing the "Medical Center" at Broadway and 168th Street, it was founded in 1876, and is affiliated with the College of Physicians and Surgeons the Medical

Department of Columbia University The Hospital moved into the present buildings in 1928 On the present site are grouped, besides the Presbyterian Hospital and the College of Physicians and Surgeons of Columbia University, the Sloan Hospital for Women, the New York State Psychiatric Institute and Hospital, the Babies' Hospital, the Squier Urological Clinic, Presbyterian Hospital and Sloane Hospital Schools of Nursing, the Neurological Institute and Hospital, the Stephen V Harkness Patient Pavilion, the School of Dental and Oral Surgery, the Vanderbilt Clinic, the Eye Institute, and the DeLamar Institute of Public Health There are 1,674 beds

FIG 8 Buildings of the Rockefeller Institute for Medical Research, New York The Laboratory Buildings are shown to the left The Hospital Building and Isolation Building are at the right in the photograph

The entire Medical Center, known as the Columbia-Presbyterian Medical Center, of which the Presbyterian Hospital is a part, covers twenty-two acres and cost \$25,000,000

Rockefeller Institute for Medical Research (York Avenue and 68th Street) The Hospital of The Rockefeller Institute for Medical Research was opened in 1910 The principles of organization of the Hospital were first, that the number of diseases studied at any one time would be limited

and only patients suffering from one or another of the diseases under investigation would be accepted, second, that all the scientific staff was to devote its entire time to the duties of the Hospital, third, that the work of the Hospital staff should consist not merely in observational studies, but in experimental studies equally, and fourth, that no charge was to be exacted from the patients for services rendered. These principles have been strictly followed. The Hospital has 60 beds and an Out-Patient Department.

New York Post-Graduate Medical School and Hospital Location 30 East 20th Street. The oldest institution in this country engaged solely in the teaching of graduate medicine, having been founded in 1882. The School was incorporated into the educational system of Columbia University

FIG 9 New York Post-Graduate Medical School and Hospital

in January 1931 and registers more than five hundred physicians annually. The Hospital maintains 410 beds and an out-patient service notable for the variety and size of its clinics. There are two extramural units: the Reconstruction Hospital with 65 beds for accident cases and conditions arising out of industrial injury and disease, and the former New York Skin and Cancer Hospital now operated as an out-patient service for skin and cancer cases only, the in-patients being hospitalized in the main hospital building. Certain wards of the Metropolitan, Willard Parker and Sea View Hospitals, and the Hospital for Joint Diseases are also used for teaching purposes.

The *New York City Department of Health* operates seventeen clinics for the diagnosis of syphilis, gonorrhea, and lymphogranuloma inguinale. Ten of these clinics are also treatment centers. Annually, about 24,000 patients make over 400,000 visits to these clinics which conduct 120 sessions per week, serving all parts of the city. For the clinical demonstration arranged for the American College of Physicians, cases will be selected from these clinics and brought to the new Health Department Building at 125 Worth Street.

THE POST-CONVENTION CRUISE TO BERMUDA

Following the New York Session, April 4-8, 1938

A specially conducted cruise for members of the College and their friends, as also announced in the News Notes section of the January issue of this Journal

FOR two sparkling days you will live in each direction on ships planned for pleasure. You'll delight in the sumptuous two-storied lounges, in the magnificently appointed smoking rooms that remind you of the best London clubs. Broad promenade decks, the unobstructed sports deck, the magnificent swimming pools, the comfortable nooks will contribute to your pleasure and relaxation aboard ship.

Gardens and Pool, Hotel Bermudiana

In Bermuda the Atlantic is at your doorstep, literally almost everywhere. The air has a salty tang, mingled with the scent of flowers. You will wish to visit the sea gardens to study the fantastic and colorful under-sea life through the glass bottom boats. You will wish to visit Leamington and Crystal Caves with their huge columns of white, translucent or pastel stalactites and stalagmites.

Hotel Bermudiana from the Bay

Sailing from New York about 3 P M on the Georgic of the Furness Bermuda Line on April 9, staying at the Hotel Bermudiana while in Bermuda, arriving back at New York about 9 A M, April 15. All inclusive tariff ranging from \$111 25 to \$151 25, according to rooms selected.

For reservations (which should be made by March 1), ship plans and full information, communicate with the Secretary of the College or directly with the Cruise Conductor, MR LEON V. ARNOLD, 36 WASHINGTON SQUARE WEST, NEW YORK CITY.

DIABETICS

LIVE LONGER

Today

THE LIFE SPAN of the diabetic has been lengthened considerably following the discovery of Insulin and the growing knowledge of its use. There is, however, a definite responsibility on the part of the physician to educate the many new diabetics in the importance of proper diet and proper use of Insulin preparations.

The apparent increase in diabetes in recent years has been attributed to the modern manner of living, increased sugar consumption, overeating and lack of muscular exercise. With proper management the great majority of patients can be kept well-nourished, sugar-free, and at work.

Insulin Squibb is an aqueous solution of the active anti-diabetic principle obtained from pancreas.

It is accurately assayed, uniformly potent, carefully purified, highly stable and remarkably free of pigmentary impurities and proteinous reaction-producing substances.

Insulin Squibb of the usual strengths is supplied in 5-cc and 10-cc vials.

Protamine Zinc Insulin, Squibb complies with the rigid specifications of the Insulin Committee, University of Toronto, under whose control it is manufactured and supplied. It is available in 10 cc vials. When this preparation is brought into uniform suspension, each cc contains 40 units of Insulin together with protamine and approximately 0.08 mg of zinc.

IN SINUSITIS AND HEAD COLDS

when you prescribe a liquid vasoconstrictor, consider three points:

1

PROLONGED EFFECTIVENESS

'Benzedrine Solution' produces a shrinkage which lasts 18 per cent longer than that produced by ephedrine.

2

MINIMUM SECONDARY REACTIONS

On continued use 'Benzedrine Solution' produces practically no secondary vasomotor relaxation.

3

REAL ECONOMY

'Benzedrine Solution' is one of the least expensive liquid vasoconstrictors

BENZEDRINE SOLUTION

Benzyl methyl carbinamine, SKF, 1 per cent in liquid petrolatum with $\frac{1}{2}$ of 1 per cent oil of lavender 'Benzedrine' is the registered trade mark for Smith, Kline & French Laboratories' brand of the substance whose descriptive name is benzyl methyl carbinomine

SMITH, KLINE & FRENCH LABORATORIES

Philadelphia, Pa

Established 1841

Remarkable release of EXCESS FLUID

● In cases of cardiac or cardiorenal disease with edema, intramuscular or intravenous injection of Salyrgan often proves a life-saving measure. Profuse diuresis usually sets in after three or four hours, and the quantity of fluid eliminated is often enormous. Amounts of 3 or 4 quarts are common and from 8 to 15 quarts may be observed.

Owing to the thoroughness with which Salyrgan acts, reaccumulation of fluid may be so controlled that it does not again assume serious proportions, and by occasional administration of Salyrgan many patients may be kept comfortable for long periods.

Salyrgan solution (containing 10% of Salyrgan) is supplied in ampules containing 1 cc (boxes of 5, 25 and 100) and 2 cc (boxes of 10, 25 and 100).

by CAMERON—pioneers in successful tube type radio knives and
Surgimold diagnostic and operating instruments

The Cauteradio provides the Physician Surgeon and Specialist with an Electro-Scalpel and Coagulator for office use at a reasonable price. The Model "O" is thoroughly practical for all minor surgery and light major surgery of the eye, ear, nose, throat, skin, vagina and rectum. It is completely equipped for monopolar cutting, monopolar coagulating, bipolar coagulating, desiccating, dehydrating and fulgurating in the office and clinic.

The instrument comes complete with all accessories and electrodes for general use, and can be provided with many additional electrodes, snares, adapters and other accessories for widening the scope in any general or special practice.

Each Cauteradio is also provided with a Boilable Cameron Surgical Cord and Rheostat Control to operate all Instruments and Lamps in Cameron's Electro-Diagnoset without the necessity of a separate Vitrohm Potential Adjuster. Cameron's Electro Diagnoset is illustrated to the right. It is a combination of electrically lighted instruments furnishing abundant light for every purpose together with the latest mechanical improvements for control of the field under examination or operation and for use in every orifice or cavity of the body. The diagnostic outlet of the Cauteradio functions independently from the cutting coagulation or bipolar outlets, and may be used with or without the balance of the instrument as desired.

Cameron Cauteradios and Cauterodynes range in price from only \$125.00 to \$550.00. All outfits are completely equipped ready to use—nothing additional to buy.

Sixteen miles east of Los Angeles In the foothills of the Sierra Madre Mountains at an elevation of 1000 feet On the main line of Santa Fe Railway Connected with Los Angeles by interurban railway and splendid boulevards

ENVIRONS

The grounds consist of a beautiful park of forty acres, in which are found a variety of native Live Oaks subtropical trees and plants and a profusion of beautiful shrubs and flowers Many winding walks and nooks of exquisite beauty add to its attractiveness When on exercise, patients also enjoy the beautiful trails in the adjoining canyons and mountains

MEDICAL CARE

Competent resident staff Examinations for comparison every six weeks Close medical supervision Individual needs and problems receive personal attention

THERAPEUTIC CARE

Fads are not followed but an endeavor is made to give patients the amount of rest and exercise suited to their individual needs the benefits of a liberal and adequate diet, such tonic measures as will increase their resistance and other measures that will help them overcome any disturbing symptoms or complications that may arise Heliotherapy tuberculin, pneumothorax and surgery employed whenever indicated

Weekly rates from \$25 00 up including medical attention medicines (except expensive remedies) and general nursing Extra charge for operative measures (except pneumothorax)

DIAGNOSTIC CLINIC

A diagnostic clinic is maintained for the study of all diseases of the chest

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts, Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physicians. The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College.

MANUSCRIPTS All correspondence relating to the publication of papers and all books and monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following style:

4 Doe, J. E. What I know about it, Jr. Am. Med. Assoc., 1931, xcvi, 2006-2008.

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations.

REPRINTS For each article published, there will be furnished gratis fifty reprints without covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are wanted the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and books bearing upon the field of internal medicine. Authors and publishers wishing to submit such material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made in the department of reviews.

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid: \$7.00, United States, Canada, Mexico, Cuba, Canal Zone, Hawaii, Porto Rico; \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. Members of the American College of Physicians receive the ANNALS OF INTERNAL MEDICINE as a part of their membership. Checks should be drawn to the order of W. D. STROUD, M.D., Treasurer, and remitted through the Publication Office or the Executive Secretary's Office.

BUSINESS CORRESPONDENCE All correspondence relating to business matters, advertising, subscriptions to the ANNALS, inquiries concerning membership in the American College of Physicians, et cetera, should be addressed to the Publication Office or to the Executive Secretary. Books and reprints presented to the College Library should be addressed to the Executive Secretary.

extract orally were able to modify human diabetes. Further evidence that the hypoglycemic action is not due to an insulin extract from the duodenum has been supplied by Zunz and La Barre⁵⁶. Using the method of pancreatico-jugular anastomosis between adrenal decapsulated dogs, they obtained a lowering of blood sugar after intravenous injection of non-hypotensive secretin in the donor that was much less marked than that in the recipient. This, of course, would not be expected to occur, if the extract were insulin.

Other differences in the action of the duodenal extracts as compared with insulin may be noted in the work of still other investigators. Thus, Takacs⁵² reports that in many instances his duodenal extract produced a very conspicuous reduction of blood sugar (50 to 60 per cent) without the phenomena that go with insulin hypoglycemia. Such hypoglycemic phenomena did not appear even after the administration of very large doses of the extract. Duncan¹⁸,¹² too, recently remarked the fact that while they found their extract of value in reducing a marked hyperglycemia in human diabetics, they never saw any hypoglycemic reactions from the use of the extract. And Novao Santos⁴⁷ reports a case of a controlled diabetic in whom the injection of secretin produced, after two hours, a blood sugar of 38 mg per 100 c.c., with no symptoms of a hypoglycemia. Takacs⁵² also points out the much greater duration of the effect of his extract as compared with that of insulin. Secretin, from this standpoint the observations of La Barre and Ledrut²⁷ and of Haston¹⁰²⁸ are also of interest. These investigators found that not only were they able to keep depancreatized dogs alive by the oral administration of the duodenal preparation, but also that they did not find it necessary to compensate for the absence of pancreatic ferments—a procedure which was indispensable in the treatment of a depancreatized animal with insulin.

He noted
at the d

III IS THE HYPOGLYCEMIC EFFECT OF DUODENAL EXTRACTS DUE TO ISLET STIMULATION?

In 1924, Troteano,⁵³ on the basis of experiments on dogs, concluded that the transitory hypoglycemic effect which follows the intravenous injection of secretin results from the stimulation of the insular apparatus of the pancreas. Many investigators since have supported this view. Dale⁹ as far back as 1905 observed in both mammals and amphibia an increase in the number and volume of the islets of Langerhans after repeated injections of secretin. This work of Dale's was referred to in the report of Laughton and Macallum,³² made a quarter-century later. These investigators found that animals receiving their duodenal preparation daily, over a period ranging from a week to 10 days, showed the effect on artificially induced hyperglycemia for two weeks following the last injection. This result they explain in terms of the islet-stimulation concept. Macallum³⁵ had previously postulated that diabetes might result from insular fatigue.

occasioned by the excessive stimulation of the islets by the duodenal hormone. Freud and Saadi-Nazim¹⁵ in 1926 further confirmed Troteano⁵³ by their results from the duodenal instillation of hydrochloric acid in dogs. In the same year, Dixon and Wadia¹⁰ demonstrated the increase in pituitrin in the cerebrospinal fluid of dogs following the injection of duodenal extracts, a reaction which they believed to be of the same nature as that which followed injections of insulin. The following year Fieschi,¹⁴ using secretin manufactured by the original Bayliss and Starling formula, noted that the sugar tolerance in dogs whose diet was rigorously controlled increased after prolonged treatment with secretin. Fieschi injected 10 cc three times a day for nearly 30 days. He noted that some of the animals which had a low tolerance at the beginning of treatment almost doubled their tolerance to ingested sugar by the end of the treatment. Uselli⁵⁴ believed that the hyperemia of the pancreas which followed the injection of secretin, or the introduction of hydrochloric acid into the duodenum, determined the hyperactivity of both the external and insular secretory mechanism.

Gley and Hazard¹⁶ from transfusion experiments following the duodenal instillation of hydrochloric acid concluded that the mechanism involved was islet stimulation. Finally, La Barre and Houssa²⁶ studied the effect of secretin produced in the duodenum upon a pancreas the exocrine portion of which had been destroyed. Injected into the duodenum of a dog whose external pancreatic ducts had been ligated one to two months previously, and in which a bilateral suprarrenal^{mes} had been performed just before the injection, these investigators^{ar, but} gradual hypoglycemia as marked in these animals as in those with a^{1,400} pancreas. They obtained a similar response even when the ex^{es, Can't} for bac^{tion} of the pancreas adhering to the duodenum was removed and t^{time, when} portion maintained as an abdominal subcutaneous graft.

The above cited investigations appear to^{the order} that the blood sugar reducing factor present in duodenal extracts operates through islet stimulation. To prove absolutely that this is the sole mode of action of the duodenal extract it would be necessary to show that it could not alter blood sugar without the aid of the pancreatic islet tissue. The obvious approach was the study of its action in the totally depancreatized animal.

IV IS THE HYPOGLYCEMIC ACTION OF DUODENAL EXTRACTS DUE TO A SEPARATE DUODENAL HORMONE?

Oehme and Wimmers³⁹ in 1923 reported a hypoglycemic effect from secretin in four depancreatized dogs. The following year Ivy and Fischer²² obtained an insulin-like substance from the duodenal mucosa with which they were able to reduce the blood sugar in a depancreatized dog. Penau and Simonnet^{41, 42} reported similarly. Takacs⁵² found his duodenal preparation effective in depancreatized animals when administered intravenously, subcutaneously, orally or by rectum. La Barre and Still²⁴ also reported

the efficacy of crude secretin in lowering the blood sugar of totally diabetic dogs, and La Barre and Ledrut²⁷ were able to obtain through the hydrolysis of secretin, a non-secretagogic fraction which was especially effective in reducing the blood sugar of depancreatized animals. Other observers such as Novao Santos,^{15, 46} Criado,⁸ Laughton, Macallum, Rabinowitch and Watson,³¹ and Laughton and Macallum³² were unable to influence the blood sugar of depancreatized animals with their duodenal extracts. In such investigations, however, positive findings, if repeated, are more significant than negative results.

V IS THE HYPOGLYCEMIC ACTION OF DUODENAL EXTRACTS A COMBINATION OF ISLET STIMULATION AND DIRECT ACTION?

While the results obtained by certain investigators in the depancreatized animals indicate that the duodenal extracts are capable, alone, of reducing the blood sugar, there is some evidence that in the intact animal they enhance islet activity as well. Zunz and La Barre⁵⁷ have shown that secretin can increase the output of insulin. Using adrenalectomized dogs with pancreatico-jugular anastomoses, they found that purified secretin injected into the donor dog caused a drop in blood sugar in both the donor and recipient, with the fall more marked in the latter. Since in this experiment, the donor is physiologically depancreatized, the above results may be interpreted as a double action of the secretin. This concept is fortified by their findings with jugulo-jugular anastomosis: the injection of secretin into the donor produced only a slight decline in the donor, while the recipient which was less marked than that which occurred in the donor. La Barre and Still reported confirmation of some of these experiments.

Additional suggestive data for the dual action are to be found in the results of Takacs⁵². He noted that depression of the blood sugar following the administration of the duodenal preparation lasted a much shorter time in the depancreatized animal than in the intact one. Clinically, too, both Laughton et al³¹ and Duncan and his associates¹² report their best results with the Laughton-Macallum extract in the milder cases of diabetes.

Our experiments in human beings offer data which do not seem to confirm exactly the probable mechanism as observed in lower animals. It is, of course, impossible to duplicate in man the experimental conditions of animals which permit a study of the effect on the blood sugar of duodenal stimulation in the absence of the pancreas. The closest simulation to such conditions probably was obtained in our case in chart 7. Unfortunately, this man who appeared to have a diffuse calcification of the pancreas was available for only a few studies. It would appear from comparison of chart 7 with the remaining charts that, in man, by far the major effect on the blood sugar of duodenal stimulation is due to islet stimulation rather than to the direct action of a duodenal hormone. This is supported by the greater efficacy of duodenal extracts in the milder cases of clinical diabetes.

THE RELATIONSHIP OF THE HYPOGLYCEMIC DUODENAL FACTOR TO THE AUTONOMIC NERVOUS SYSTEM

Despite the studies of Zunz and La Barie¹⁷ which showed that vagotomy does not prevent the action of the sugar reducing factor in injected duodenal extracts, it would appear from the work of Heller²⁰ that some of this action

CHART 1

Curve A = Blood sugar readings (F) fasting and at 15 and 30 min after the ingestion of 225 c.c. of 38.4% glucose. No duodenal instillation. Total glucose lost from stomach in 30 min = 25.5 gm.

Curve B = Blood sugar readings (F) fasting and at 15 and 30 min after the duodenal instillation of 20 gm of glucose in isotonic solution.

Curve C = Blood sugar readings (F) fasting and at 15 and 30 min after the ingestion of 225 c.c. of 41.5% glucose and simultaneous duodenal instillation of 0.47% HCl at 100 gtt/s per min. Total glucose lost from stomach in 30 min = 20.6 gm.

was dependent upon intact vagi. This investigator found, by chemical elimination of the vagus by atropine and of the sympathetics by ergotamine, that while the action of the intestinal extract was retained, its effect was reduced.

Whether the duodenal extracts are able to influence adrenalin hyperglycemia is not quite clear. Laughton and Macallum²² report a marked lowering of the level of adrenalin hyperglycemia in rabbits and dogs by

injection of the duodenal extract Hellei²⁰ saw an effect from his extracts under similar conditions, but not a very distinct one

We are not familiar with any previous studies on man of the influence of direct duodenal stimulation on hyperglycemia so produced We studied this effect in 10 patients After intubation of the duodenum of a fasting subject we injected 10 minims of adrenalin chloride (1-1000) subcutan-

CHART 2

Curve A = Blood sugar readings (F) fasting and at 15 and 30 min after the duodenal instillation of 25 gm of glucose in isotonic solution

Curve B = Blood sugar readings (F) fasting and at 15 and 30 min after the duodenal instillation of 62.5 cc of 40% glucose (25 gm)

Curve C = Blood sugar readings (F) fasting and at 15 and 30 min after the duodenal instillation of 500 cc of 5% glucose (25 gm) in 0.3% HCl

eously, having previously taken blood for sugar determination Blood samples were taken at 15 minute intervals for one hour during which nothing was instilled into the duodenum On a subsequent day the same procedure was repeated, except that, in addition, the duodenal instillation of 0.4 per cent hydrochloric acid at the rate of 60 to 80 drops per minute was started simultaneously with the injection of the adrenalin, and was continued throughout the hour of the test period On still another day the duodenal instillation of the acid was started 15 minutes before the injection of the adrenalin Charts 8 and 9 illustrate the results obtained, the former in a patient with a normal gastric secretion, the latter in a case of anacidity

In chart 8, we note that the subcutaneous injection of 10 minims of adrenalin chloride (1-1000) after an overnight fast produced a change in glycemia from 98 mg to 178 mg per 100 c c in the course of an hour, a rise of 85 mg. Under similar conditions of adrenalin action, the simultaneous instillation of 0.5 per cent hydrochloric acid at the rate of 60 drops per minute during the course of the hour, resulted in a change in blood sugar concentration from a fasting level of 87 mg to 186 mg per 100 c c, a rise

CHART 3

Curve *A* = Blood sugar readings (*F*) fasting and 15 and 30 min after the ingestion of 225 c c of 38.4% glucose. No duodenal instillation. Total glucose lost from stomach in 30 min = 25.5 gm.

Curve *B* = Duodenal instillation of 0.47% HCl at 100 drops per min for 15 min. Acid stopped. Then duodenal instillation of 500 c c of 5% glucose (rapidly). Blood sugar (*F*) fasting at 15 and 30 min after the instillation of the glucose (25 gm).

Curve *C* = Duodenal instillation of 0.47% HCl at 100 drops per min for 15 min. Acid stopped. Then duodenal instillation of 50 c c of 50% glucose. Blood sugar (*F*) fasting and at 15 and 30 min after the instillation of the glucose (25 gm).

of 99 mg per 100 c c of blood. Starting the duodenal instillation of the acid 15 minutes before the injection of the adrenalin did not alter the result. The changes in chart 9 parallel those recorded in chart 8. Similar results were obtained in all of the 10 cases studied. It is, therefore, evident that duodenal stimulation in man is not capable of modifying adrenalin hyperglycemia.

THE EFFECT OF DUODENAL STIMULANTS OTHER THAN HYDROCHLORIC ACID IN THE PREVENTION OF ALIMENTARY HYPERGLYCEMIA

Bayliss and Starling¹ at first believed that the action of the hydrochloric acid was essential to the extraction of active secretin from the mucosa. It was soon learned, however, that many agents, such as soap, chloral hydrate, sodium chloride, sugar, alcohol, acetone and others, could extract an active secretin under similar conditions.

CHART 4

Curve A = Blood sugar readings fasting (F) and at 15 and 30 min after the ingestion of 225 cc of 40.8% glucose. No duodenal instillation. Total glucose lost from stomach in 30 min = 26.4 gm.

Curves B, C, D and E = Blood sugar readings fasting (F) and 15 and 30 min after the ingestion of 225 cc of 40% glucose and simultaneous duodenal instillation of 0.45% HCl at 60, 70, 80 and 100 drops per min respectively. Total glucose lost from stomach in 30 min = 19.9, 18.2, 20.9 and 23 gm respectively.

Curve F = Blood sugar readings fasting (F) and at 15 and 30 min after the duodenal instillation of 23 gm of glucose in isotonic solution.

We⁴⁸ have shown, too, that the intrinsic agent which activates the local duodenal mechanism concerned in the motor activity of the stomach and pylorus, is the gastric hydrochloric acid. It was also pointed out that other substances added in food, which were through chemical or physical action capable of stimulating the duodenal mucosa, could also effect pyloric closure. The present studies were, therefore, extended along these lines and the action of fats, isotonic and hypertonic solutions of sodium bicarbonate and sodium chloride, as well as hypertonic solutions of glucose were investigated. Chart 5 illustrates the effects produced by these various

substances instilled into the duodenum while glucose is being absorbed from the stomach. With oil, hypertonic bicarbonate or hypertonic saline solutions, effects are seen which are identical with those obtained from the duodenal instillation of hydrochloric acid. They consist, as before, of no appreciable rise in blood sugar during the period of duodenal instillation even though quantities of glucose are being absorbed from the stomach which would ordinarily cause a sharp rise in blood sugar. (Curve 4, chart 5.) Chart 6 illustrates a similar action of fat in our diabetic patient

CHART 5

Curve A = Blood sugar readings fasting (*F*) and at 15 and 30 min after the duodenal instillation of 23 gm of glucose in isotonic solution

Curve B = Blood sugar readings fasting (*F*) and at 15 and 30 min after the ingestion of 225 cc of 40.8% glucose. No duodenal instillation. Total glucose lost from stomach in 30 min = 26.4 gm

Curve C = Blood sugar readings fasting (*F*) and at 15 and 30 min after the ingestion of 225 cc of 40% glucose and simultaneous duodenal instillation of 0.45% HCl at 60 gtts per min. Total glucose lost from stomach in 30 min = 19.9 gm

Curve D = Blood sugar readings fasting (*F*) and at 15 and 30 min after the ingestion of 225 cc of 41.0% glucose and simultaneous duodenal instillation of 5% NaCl at 80 gtts per min. Total glucose lost from stomach in 30 min = 21 gm

Curve E = Blood sugar readings fasting (*F*) and at 15 and 30 min after the ingestion of 225 cc of 40.5% glucose and simultaneous duodenal instillation of olive oil 80 gtts per min. Total glucose lost from stomach in 30 min = 20.2 gm

Curve F = Blood sugar readings fasting (*F*) and at 15 and 30 min after the ingestion of 225 cc of 39.8% glucose and simultaneous duodenal instillation of sod bicarb (7%) 60 gtts per min. Total glucose lost from stomach in 30 min = 24.2 gm

Charts 2 and 3 indicate that glucose itself in hypertonic solution in the duodenum calls forth the same mechanism as do other agents. Thus in chart 2, one sees after the duodenal instillation of 25 grams of glucose in isotonic solution a rise in blood sugar from a fasting level of 93 mg to 185 mg in a half hour, a rise of 92 mg of glucose per 100 cc of blood (curve A). When the same amount of glucose in hypertonic solution (40 per cent) is instilled into the duodenum on another day the change in blood sugar concentration in the following half hour is distinctly less marked

CHART 6

Curve *A* = Blood sugar readings fasting (*F*) and at 15 and 30 min after the ingestion of 225 cc of 38.5% glucose. No duodenal instillation. Total glucose lost from stomach 38.6 gm in 30 min.

Curve *B* = Blood sugar readings fasting (*F*) and at 15 and 30 min after the duodenal instillation of 25 gm of glucose in isotonic solution.

Curve *C* = Blood sugar readings fasting (*F*) and at 15 and 30 min after the ingestion of 225 cc of 41.7% glucose and simultaneous duodenal instillation of olive oil 60 gtts per min. Total glucose lost from stomach in 30 min = 18.5 gm.

Curve *D* = Blood sugar readings fasting (*F*) and at 15 and 30 min after the ingestion of 225 cc of 40.0% glucose and simultaneous duodenal instillation of 0.47% HCl at 80 gtts per min. Total glucose lost from stomach in 30 min = 31.5 gm.

CHART 7

Curve *A* = Blood sugar readings fasting (*F*) and at 15 and 30 min after the ingestion of 225 cc of 41.7% glucose and simultaneous duodenal instillation of 0.47% HCl at 80 gtts per min. Total glucose lost from stomach in 30 min = 27.6 gm.

Curve *B* = Blood sugar readings fasting (*F*) and at 15 and 30 min after the duodenal instillation of 25 gm of glucose in isotonic solution.

Thus the rise was from 96 mg to 158 mg, a change of 62 mg per 100 c c of blood (curve B). One sees also in this chart (curve C) how much greater is the stimulating action of 0.3 per cent hydrochloric acid. When the 25 grams of glucose in isotonic concentration are made up in 0.3 per cent hydrochloric acid and instilled into the duodenum, the subsequent change in blood sugar is the least in this group of experiments, a change this time from a fasting level of 88 mg to 129 mg, a rise of only 41 mg of glucose per 100 c c of blood.

CHART 8

Normal gastric acidity (1) Blood sugar curve after 10 min of adrenalin chloride (1-1000) subcut (2) Same as (1) plus 0.51% HCl intraduodenally 60 gts per min

Chart 3 also strikingly illustrates the difference in action of relatively isotonic glucose and markedly hypertonic solutions. Thus for curve B, 0.47 per cent hydrochloric acid was instilled into the duodenum at the rate of 100 drops per minute, for 15 minutes. The acid was then stopped and 500 c c of 5 per cent glucose rapidly instilled into the duodenum. The blood sugar before the instillation of the glucose was 100 mg per 100 c c. One-half hour after the glucose the blood sugar had risen to 169 mg, a change of 69 mg per 100 c c of blood. The experiment repeated (curve C) with the exception that the 25 grams of glucose were now instilled into the duodenum in a 50 per cent solution, produced a change in blood sugar

concentration in the following half hour of only 6 mg per 100 c c of blood. Chart 3 also indicates that the hypoglycemic action resulting from duodenal stimulation is probably effective only so long as the duodenal stimulant is applied to the mucosa, or at least not after the stimulation is adequately diffused or diluted. Curve A in chart 3 was obtained in the half hour after the ingestion of 225 c c of 38.4 per cent glucose. At the end of the half hour an analysis of the recovered gastric contents indicated that 25.5 grams of glucose had either been absorbed or had entered the duodenum. The blood sugar concentration changed from a fasting level of 100 mg per 100 c c to 188 mg, a rise of 88 mg per 100 c c. In curve B we find that the

CHART 9

Gastric anacidity (1) Blood sugar curve after 10 min of adrenalin chloride (1-1000) subcut (2) Same as (1) plus 0.51% HCl intraduodenally 60 gtts per min

preceding instillation of 0.47 per cent hydrochloric acid had little effect upon the rise of the blood sugar level following the duodenal instillation of 500 c c of 5 per cent glucose, a total amount of glucose comparable to that which had been utilized previously. This is significant when compared with the results recorded for example in chart 1, where the hydrochloric acid action upon the duodenal mucosa was maintained during the period of glucose absorption. In curve B of chart 3, the stimulating effect of the hydrochloric acid upon the duodenal mucosa was rapidly diluted by the introduction of a large amount of relatively isotonic glucose, which in itself has no local stimulating action. Curve C, chart 3, on the other hand, shows a sharply contrasting result even though the same total quantities of

hydrochloric acid and glucose were used. In this instance, however, the stimulating mucosal effect of the hydrochloric acid instead of being dissipated, is if anything, enhanced by the markedly hypertonic glucose solution. We see, therefore, in curve C, a result as definite as if continued duodenal stimulation had been maintained.

SUMMARY

A brief historical survey is furnished of the development of our knowledge of the results of duodenal stimulation beginning in 1825 when Leuret and Lassaigne observed the pancreatic effect of acid applied to the ampulla of Vater in the horse and dog. Various steps led up to the discovery of secretin by Bayliss and Starling. Duodenal extracts were later shown to contain separable hypoglycemic and secretagogic agents. The literature dealing with the nature and mode of action of the hypoglycemic agent is critically analyzed.

Our method for studying this duodenal hypoglycemic mechanism in man derives from earlier studies of the gastric absorption of concentrated glucose solutions. A method is described whereby the effect of duodenal stimulation upon the utilization of the glucose absorbed from the stomach may be determined. The method of determining the effect of such stimulation upon adrenalin hyperglycemia is likewise described.

The data from our own studies appear to indicate the following:

- 1 Glucose, at least when in high concentration, may be absorbed by the human stomach.

- 2 Duodenal stimulation by hydrochloric acid will prevent a rise in blood sugar even though the amounts of sugar absorbed from the stomach would ordinarily raise the blood sugar level.

- 3 The same effect was observed in one diabetic patient but did not occur in another very severe diabetic with a calcified pancreas.

- 4 The prevention or counteraction of alimentary hyperglycemia by duodenal stimulation is shown to be not a function solely of hydrochloric acid. Other agents which could stimulate the duodenal mucosa were equally efficacious. Thus similar results were obtained with fat, hypertonic solutions of sodium chloride and sodium bicarbonate, and of glucose itself.

- 5 While duodenal stimulation could prevent alimentary hyperglycemia, peculiarly enough, it did not carry the depression of glucose concentration below the fasting level. These observations are similar to those of Laughton and Macallum who found that their duodenal extract did not reduce the blood sugar below the normal resting level after induced hyperglycemia.

- 6 Duodenal stimulation did not alter the normal fasting blood sugar level.

- 7 Duodenal stimulation failed to prevent or decrease the hyperglycemia incident to adrenalin chloride injection.

From a study of the literature on the effect of duodenal extracts and their possible method of action, we believe there is adequate evidence to show that their action is not due to secretin or to an insulin extract from the duodenum. It would appear to depend, in the dog, upon a combination of islet stimulation and direct action of a duodenal hormone upon glucose metabolism. From the results reported in the depancreatized animal, the direct action is the essential one. From our data in a severe diabetic, it would seem that, in man, the duodenal mechanism is essentially concerned with islet stimulation. It would seem, therefore, that little could be expected from the use of duodenal extracts in the treatment of diabetes in man. In the mild cases of diabetes there may be some effect from islet stimulation, in severe diabetes there is probably no effect or even an injurious one by stimulation of already severely damaged islets.

CHRONIC HYPOCHROMIC ANEMIA IN WOMEN

ITS GASTROINTESTINAL, GYNECOLOGIC, ENDOCRINE AND PSYCHIATRIC FEATURES[†]

By SOLOMON G MEYERS, M D , A HAZEN PRICE, M D , F A C P , H C
MACK, M D , LINUS J FOSTER, M D , and E A SHARP, M D ,
F A C P , *Detroit, Michigan*

So-called *idiopathic hypochromic anemia* has been frequently discussed in the literature. Most authors emphasize the hematological aspects, neglecting other important clinical features presented by patients with hypochromic anemia which seem to us to have an important etiologic bearing. Moreover, failure to take proper cognizance of these conditions in our opinion precludes the possibility of intelligent management. These conclusions are the result of studies which will be reported below. In our opinion, the term *idiopathic* as applied to hypochromic anemia is seldom justified.

The present report is based on an intensive study of 26 women with chronic hypochromic anemia, special emphasis being placed on the gastrointestinal, endocrine, gynecologic and psychiatric problems which these patients presented. Our approach to the problem along these lines was prompted by the frequent presenting complaints of "nervousness" and "indigestion" which are also emphasized in the literature in describing this condition. Our aim was to determine possible organic or functional backgrounds for these symptoms. Gynecologic surveys were, of course, imperative since our series was composed exclusively of women. Endocrine investigations were indicated by the surprising frequency with which symptoms of glandular dysfunction were encountered. Neuro-psychiatric examinations were undertaken to determine the significance of "nervous" complaints. As a group, these patients showed a striking uniformity as to symptoms, blood findings, as well as clinical behavior before and after therapy.

Nationality and Race This group represents various Caucasian nationalities. Jewish patients, although comprising 3.4 per cent of the Harper Hospital Out-Patient Department attendance, are not represented in this series. Curiously enough, also, there were no negroes, although 7.2 per cent of the clinic enrollment is colored. Conclusions as to a racial predisposition are, of course, not suggested from this small series.

Social and Economic Factors All patients of this series represent the low-income class characteristic of dispensary practice during "depression" times.

* Received for publication May 17, 1937.

From Harper Hospital and Wayne University College of Medicine, Detroit.

Age The youngest patient in this series was 22 years of age, the oldest 48 years The average age was 38 years

Period of Observation Average 27.3 months

HEMATOLOGIC FEATURES

The hematologic features of the 26 patients studied are summarized in table 1. It is worthy of note that seven, or 30 per cent, of these patients showed a macrocytosis upon admission. This morphologic characteristic is found in anemia of long duration, and is also a frequent indication of blood regeneration due to postpartum bleeding, uterine hemorrhage from fibroids, functional uterine bleeding and multiple pregnancy.

TABLE I
Hematologic Features

| | | | |
|--|-----------|-------|----------------------------|
| <i>On admission</i> | | | |
| Average hgb | 51% | Range | 33%-69% |
| Erythrocyte count | 3,600,000 | Range | 2 million to 4.5 million |
| Average color index | 0.7 | | |
| Mean diameter of red blood cells—7.7 or over | | | 7 cases—30% |
| Mean diameter of red blood cells—7.4 to 7.6 | | | 8 cases—35% |
| Mean diameter of red blood cells—7.3 or below | | | 8 cases—35% |
| Average leukocyte count | 6,200 | Range | 3,250 to 11,000 |
| <i>After treatment</i> | | | |
| Average hgb | 92.8% | Range | 65%-110% |
| Erythrocyte count | 4,660,000 | Range | 3.5 million to 5.5 million |
| Average color index | 1.0 | | |
| Good hematologic response and good clinical response | | | 12 cases—46% |
| Good hematologic response and fair clinical response | | | 5 cases—19% |
| Good hematologic response and poor clinical response | | | 8 cases—31% |
| Poor hematologic response and poor clinical response | | | 1 case—4% |

In the remaining 16 patients, normocytic and microcytic diameters occurred an equal number of times. Three of the patients showing microcytosis were sisters. All had a typical picture of idiopathic achlorhydric anemia. The appellation *idiopathic* applied to the three cases in question or to others in the microcytic group, is hardly justified since disease entities believed to be exciting or contributory causes of the anemic state were associated.

Hemopoietic improvement and favorable alteration in the patient's general physical condition were by no means parallel. While anti-anemic therapy was uniformly effective, a multiplicity of general complaints persisted during and after hemopoietic recovery. When both blood count and general condition responded favorably, iron alone was usually sufficient to cause remission of symptoms, although in a few cases liver or ventriculin was found to be helpful. On the other hand, poor or fair clinical results were not due to persistence of the anemia since little difficulty was encountered in restoring blood balance in these cases. The group, therefore,

showing indifferent general response created the impression that factors other than anemia were present. Among the most frequently associated conditions retarding full recovery were gastrointestinal disorders, endocrinopathies (particularly thyroid deficiency and entities causing excessive menstruation), and nervous system instability. In order to meet the individual therapeutic requirements of this series of patients, it is obvious that a rather comprehensive regimen had to be adopted. Among the hormones, desiccated thyroid, parathyroid extract, Antuitrin-S, Theelin and Pituitrin were employed, dietary adjustment, hydrochloric acid, laxatives and sedatives were necessary to control the gastrointestinal complaints, while snake venom, calcium, dilatation and curettage, and induction of menopause by radiation or surgical procedures were used in an effort to control the gynecologic conditions. Social adjustment was encouraged by appropriate psychotherapeutic methods.

It is evident that anemia is an expression of disease and seldom exists as a solitary clinical entity. It is equally obvious, then, that its corrective measures cannot be restricted to any one specific group of medicament. Numerous therapeutic endeavors are required in the comprehensive management of the anemic patient. Hence in planning treatment, this concept should govern the hematologist and clinician.

GASTROINTESTINAL FEATURES

Atrophy of the lingual papillae with the production of a smooth tongue was present in 25 per cent of our cases. An additional 12 per cent complained of burning of the tongue in the absence of atrophy.

The gastric acidity was determined one or more times in each case (see table 2). True achylia, with no response to alcohol ingestion or histamine injection, was present in 54 per cent, false achylia (no free acid after alcohol meal, but present after histamine injection) in 12 per cent, and hypoacidity (free acid 0 to 20) in 15 per cent. Acidity was less than normal, therefore, in 81 per cent of our cases. The crucial role which free hydrochloric acid plays in the digestion and utilization of blood building elements from food has been pointed out by Mettler, Kellogg and Rhinehart¹.

Gastrointestinal symptoms have been repeatedly described in this disease, usually being referred to as "indigestion" or "dyspepsia." An attempt was made to analyze more exactly the nature of the dyspepsia by the use of clinical and roentgenologic methods. Table 2 reveals the gastrointestinal diagnoses made in our series. Seventy-three per cent of the patients had disturbances of colonic function of the type usually referred to as unstable colon (Kantor²) or irritable colon (Jordan and Kiefer³). This condition is marked by pain in any portion of the abdomen, never severe but present over long periods of time, and often accompanied by belching, a

sensation of distention, constipation, diarrhea, or alternating constipation and diarrhea

The digestive symptoms were often the outstanding ones, overshadowing the evidence of anemia. Treatment which raised the blood levels to normal did not as a rule alleviate the dyspepsia. The digestive disorder may also be a cause for failure of treatment or for immediate recurrence of anemia since these patients often choose a bland diet, high in starches and low in meats, vitamins and iron containing vegetables. The caloric intake may also be low because of the distress occasioned by food, and the cathartics frequently taken may interfere with absorption.

TABLE II
Digestive Symptoms

| | | |
|---|--|-----------------|
| A | Tongue smooth | 25% |
| | Tongue not atrophic but complains of burning | 12% |
| | Tongue not atrophic | 63% |
| B | Gastric acidity | |
| | True achylia | 54% |
| | (No free acid after alcohol or histamine) | |
| | Pseudo achylia | 12% |
| | (No free acid after alcohol, free acid present on histamine injection) | |
| | Hypoacidity | 15% |
| C | (Free acid after alcohol 0° to 20°) | |
| | Normal acidity (20° to 40°) | 15% |
| | Hyperacidity (40° and over) | 4% |
| | Gastrointestinal diagnoses | |
| | Irritable colon | 19 cases, (73%) |
| | Constipation, no subjective symptoms | 2 cases |
| | Internal hemorrhoids | 4 cases |
| | Probable cholecystitis | 3 cases |
| | Chronic appendicitis | 1 case |
| | Oxyuris infestation | 1 case |
| | Indigestion, unclassified | 1 case |
| | No gastrointestinal symptoms | 3 cases |

In addition to colonic disturbances, other gastrointestinal conditions were also present, such as internal hemorrhoids, cholecystitis and oxyuris infestation. Only three patients (12 per cent) did not complain of gastrointestinal symptoms.

Because of the frequent occurrence of irritable colon, our patients were routinely given a diet high in meat and green vegetables, in which the gas producing foods as cabbage, cucumbers, raw apple, fried and spicy foods were eliminated (see anti-anemic diet). Other agents were frequently employed: anti-spasmodics (belladonna), sedatives (bromide or phenobarbital), and mineral oil by mouth, or olive oil by retention enema. The gastrointestinal symptoms were quite satisfactorily controlled by this type of management.

All patients with deficient gastric acidity were given dilute hydrochloric acid. Occasionally a case was noted where the dyspepsia disappeared immediately after the addition of acid therapy.

Following the suggestion of Gray and Wintrobe,⁴ a dietetic history was taken to reveal the food intake during the development of the anemia. The following dietary abnormalities were noted:

| | |
|--------------------------|-----|
| Low meat and iron intake | 32% |
| Low calcium intake | 49% |
| Low vitamin A | 4% |
| Low vitamin B and C | 36% |
| High starch intake | 44% |

These figures are not surprising when one considers that we are dealing here with clinic patients in depression years.

In general, patients on a low meat diet also ate other foods low in iron. About half the patients had a low calcium intake, a situation not peculiar to anemic patients since it has been shown that adults generally have a negative calcium balance, the patients drawing on the reserves of these substances stored in bone.

The low fruit and vegetable intake caused not only a deficiency of iron but also of vitamins B and C. The high starch diet taken by 44 per cent of the patients is common in the average American dietary.

The diet list routinely given to our patients was designed to increase the meat and iron intake, and to provide adequate minerals, vitamins and calories.

ENDOCRINE FEATURES

(a) *Thyroid Function* Thyroid function was determined by clinical signs and symptoms, determination of the basal metabolic rate and by response to thyroid therapy. Results of the survey showed:

| | |
|--|---------------|
| Normal thyroid function | 12 cases, 48% |
| Hypothyroidism | 12 cases, 48% |
| Low metabolic rate without hypothyroidism (no data, 1 case) | 1 case, 4% |

Hypothyroidism was present in about one-half of our patients and was moderate in degree, there being no cases of myxedema. Two patients with hypothyroidism had had previous thyroidectomies. In many, the hypothyroidism would have remained undiscovered unless looked for specifically. Basal metabolic rates were only of corroboratory value, seven of the 12 having rates from 0 to —10, and five from —11 to —20, none were below —20. A single case had a low basal rate (—17 per cent) without clinical hypothyroidism, her condition became worse on the administration of thyroid extract.

Anemia accompanying myxedema is well known and will often respond to thyroid extract where iron therapy is unsuccessful. It is our opinion that minor degrees of hypothyroidism play some role in the production of anemia, perhaps because the rate of iron metabolism is diminished.

Patients with anemia frequently manifest symptoms bearing a marked resemblance to those of hypothyroidism, namely fatigue, dry skin, brittle nails, and abnormal sensitivity to cold weather. A further resemblance is that the basal metabolic rate is said to be lowered in anemia. The clinical survey of the patient for evidences of hypothyroidism was made after the anemia had been wholly or largely corrected by anti-anemic therapy, metabolic rate determinations were again made when the blood had reached a normal or almost normal level. Another criterion for the diagnosis of hypothyroidism was a favorable response to thyroid medication. Demonstration of hypothyroidism was important since clinical improvement resulted from the administration of thyroid extract in patients who were persistently fatigued even after the blood level had been brought back to normal.

OBSTETRICAL AND GYNECOLOGICAL FACTORS

(a) *Menstrual Function* Of the 26 patients, 17 (65 per cent) gave a history of marked menorrhagia. Two (8 per cent) had moderate menorrhagia, and the remaining seven (27 per cent) had menstruated normally. Eight patients had reached or were approaching the menopause, two had artificial menopause induced by us because of excessive vaginal bleeding, one by irradiation, one by surgical measures.

Of the 19 who menstruated profusely, 10 (55 per cent) had normal thyroid function, and 9 (45 per cent) had signs and symptoms of hypothyroidism. It is generally believed that menorrhagia is more commonly associated with hypothyroidism than with hyperthyroidism. One of our patients, however, complained of menorrhagia while hyperthyroidism was present, when hypothyroidism developed after her fourth thyroid operation, menorrhagia persisted to such a degree that artificial menopause was induced by irradiation.

(b) *Multiple Pregnancy* The factor of multiple pregnancy was present in five cases, four patients had had 10 or more pregnancies, and one patient had had six pregnancies within six years.

Pregnancy not only is an important etiologic factor in the anemia but also an important one in causing relapse of anemia in patients who are under control. One patient who had borne eight children before coming under our care had her blood levels brought up to normal, only to relapse in each of the two subsequent pregnancies.

(c) *Gynecological Factors* No organic causes for vaginal bleeding could be demonstrated in the entire group. Five (18 per cent) were subjected to dilatation and curettage to rule out the organic causes for the bleeding. The whole group presented the usual run of minor gynecological pathology such as endocervicitis, trichomonas vaginalis vaginitis, cystocele, atrophic vaginitis. None of these were thought to have any bearing on the vaginal bleeding or anemia.

Other types of endocrine therapy, aside from thyroid extract, were used in nine cases. Theelin was administered to five patients to counteract meno-

pausal symptoms Antuitrin-S was given to two patients to diminish the menstrual flow In one case the periods became more regular, though without diminution in the quantity of blood lost In another, 55 injections of Antuitrin-S (averaging 2 c.c. per injection) were given In addition, she received Theelin, Pitocin, surgical Pituitrin, parathyroid extract, and injections of snake venom, all without effect on the menorrhagia Curettage showed a normal premenstrual endometrium We are considering temporary roentgen-ray castration In several of our patients the menstrual flow became normal after the administration of iron alone

NEURO-PSYCHIATRIC FEATURES

Previous writers have characterized patients with hypochromic anemia as suffering from nervousness, fatigue, and a worrisome disposition In an attempt to classify this nervousness more exactly, our patients received a neuro-psychiatric survey

None of our patients showed objective neurological findings This is in great contrast to our cases of treated pernicious anemia who had many neurological findings though few somatic complaints In the hypochromic group there was a multiplicity of complaints of a widely varying nature

TABLE III
Psychiatric Status

| | |
|---|-----------------|
| (a) No nervous complaints | 5 cases |
| (b) Complaints proportionate to physical ailments | 3 cases |
| (c) Mild anxiety state | 2 cases |
| (d) Anxiety neurosis | 4 cases |
| (e) Asthenia, hypochondriac type | 2 cases |
| Total with normal personality | 16 cases or 64% |
| Constitutional psychopathic inferiority | 6 cases or 24% |
| Psychasthenia | 1 case or 4% |
| Menopausal psychosis | 1 case or 4% |
| Manic depressive psychosis | 1 case or 4% |
| (No psychiatric survey, 1 case) | |

Table 3 shows the status of 25 patients who received psychiatric study This shows that one-fourth of the patients fall into the class of *constitutional psychopathic inferiority* Such persons have difficulty in adjusting themselves to the ordinary problems of life Their inability to adjust results in fixation upon numerous minor physical complaints to which the average individual would give no audience Of the six patients classified as *constitutional psychopathic inferiors*, four were of the hypochondriac type with mental depression and centering of maladjustment on somatic complaints, the remaining two were of the inadequate personality type, with inability to adjust to the ordinary rigors of life and resorting to fixation on somatic complaints as an escape from reality These patients were particularly difficult to treat because they lack insight into their problems

In the group classified as having a normal mentality, there were only five (20 per cent) who had no nervous complaints, three (12 per cent) had nervous complaints which were justified by their physical ailments. The remaining eight cases (32 per cent) with normal personalities had encountered domestic and financial situations during the period of treatment that caused emotional states of the anxiety type.

There were two cases of true psychosis, one of menopausal psychosis with paranoid trends, the other was a patient with manic depressive psychosis who later committed suicide.

The large number of patients with constitutional psychopathic inferiority, and also those with a normal personality but with anxiety neurosis, accounts for the poor clinical response to therapy despite the attainment of normal blood levels.

Only eight patients were free of nervous complaints or had nervous complaints which could be referred directly to the anemia. This group obtained subjective relief as soon as the anemia was corrected.

CAUSES OF THE ANEMIA

Table 4 shows the important etiologic factors in the anemia. As the table indicates, among the common factors are (1) diet deficient in meat and iron, (2) deficient gastric acidity and other gastrointestinal disturb-

TABLE IV
Probable Causes of the Anemia

| | |
|-----------------------------------|---------------|
| (a) Deficient meat or iron intake | 8 cases, 32% |
| (b) Deficient acidity | 21 cases, 81% |
| (c) Hypothyroidism | 12 cases, 48% |
| (d) Profuse menorrhagia | 17 cases, 65% |
| (e) Other forms of bleeding | 6 cases, 23% |
| 1 Post partum | |
| 1 Post abortive | |
| 4 Hemorrhoidal | |
| (f) Multiple pregnancy | 5 cases, 18% |
| 10 or more pregnancies | 4 cases |
| 6 pregnancies in a 6-year period | 1 case |

ances, (3) hypothyroidism, (4) multiple pregnancy, (5) excessive uterine bleeding or bleeding from other sources. More than one of these factors was present in almost every instance, there being an average of 2.6 causes for each case.

The factor of a chronic defect in alimentary function suggested by Gray and Wintrobe⁴ to explain this type of anemia is included under (2) above, but at present defies measurement.

A comprehensive concept to fuse the multiplicity of factors present in a single case is provided by Haden⁵ when he uses the term *multiple nutritional deficiency disease*, defined as a defect in the intake, absorption and utilization of blood building factors. He also includes increased body need,

such as hypermetabolism in hyperthyroidism, and deficient utilization as in chronic nephritis

DIET FOR PATIENTS WITH ANEMIA

Directions

Include in the diet every day

- 1 Fruits—especially oranges, grapefruit, prunes, apricots, peaches, etc
- 2 Vegetables—at least one cooked and one raw vegetable daily, as spinach, lettuce, beet greens, carrots, etc , and dried vegetables as peas, beans, lentils
- 3 Cereals—preferably whole grain
- 4 Bread—preferably whole grain
- 5 Eggs
- 6 Meats—red meats roast beef, beef steak, beef heart, etc , liver, kidney, sweetbreads, brain or tripe
- 7 Milk—should have at least 1 pint daily

Breakfast

Fruit
Cereal
Eggs
Toast—butter
Milk

Dinner

Red meat or liver
Potato or substitute
Vegetable (cooked)
Salad of vegetable or fruit
Bread—butter
Dessert
Milk

Supper

Choose from
dinner list

Do not include

- 1 Condiments, pickles, relishes
- 2 Fried foods, cakes, pastries
- 3 Cabbage, cucumbers, radishes, onions, raw apples
- 4 No canned or preserved fish

ASSOCIATED DISEASES

In addition to the diseases already mentioned, five patients (19 per cent) had hypertension or cardiac disease, seven (27 per cent) had arthritis or neuritis, and two (8 per cent) had positive blood Wassermann tests. In neither case with a positive serologic test was syphilis thought to be an etiologic factor in the anemia, nor was anti-luetic treatment alone sufficient to correct the anemia. There were no clinical signs of lues in either case. In one the anemia relapsed when the patient discontinued iron therapy, and in the other a hysterectomy was necessary because of repeated menorrhagia.

SUMMARY

1 A group of 26 women with hypochromic anemia was observed over a period of 27 months.

2 The term *idiopathic hypochromic anemia* is not recommended since the following factors occurred so frequently that they were thought to be of etiologic significance: deficient meat and iron intake, deficient gastric acidity and other digestive disturbances, hypothyroidism, multiple pregnancy, menorrhagia and other forms of bleeding.

3 The blood levels rose to normal under anti-anemic therapy although many of the patients continued to complain. Satisfactory clinical improvement was obtained only when a comprehensive program of gastrointestinal, endocrine and psychiatric treatment was instituted in addition to hemopoietic therapy.

4 The "indigestion" so frequently present was found to be due to spastic or irritable colon

5 The "nervousness" was frequently due to an anxiety state, yet 24 per cent were classified as *constitutional psychopathic inferiors*

Thanks are due to the Anemia Laboratory established by Parke Davis & Co., to Mr Emil Schleicher for technical hematologic assistance, to Miss Thelma Larsen for sociologic data, and to Miss Gertrude Henry for dietetic supervision

FEVER THERAPY IN THE TREATMENT OF ACUTE RHEUMATIC FEVER

By F LOWELL DUNN, M D, F A C P, and E E SIMMONS, M D,
Omaha, Nebraska

At the Fever Therapy Department of the University of Nebraska 172 arthritis patients have received treatments with the Kettering hypertherm cabinet † Of these 12 were diagnosed as acute rheumatic fever This small group, together with three cases from the University of Colorado, furnish the material for this report ‡

The table gives a summary of the cases, eight of which are described in somewhat greater detail in the text Since our primary interest was the effect of fever therapy upon the course of rheumatic fever we have excluded the frequent borderline cases in which there is often clinical disagreement as to whether the disease is rheumatic fever, atrophic arthritis, or a combination of both This fact accounts for the large number of cardiac lesions in the group The joint manifestations were confined largely to the larger joints and there was no residual joint damage except for one case (P M) In six cases there were recurrent attacks of joint involvement similar to those in which fever therapy was tried

There were eight females and seven males The ages varied from nine to 48 years Ten were febrile on admission to the hospital Eight had leukocyte counts of over 10,000 on admission Three had tonsillectomies in addition to fever therapy In six a diagnosis of mitral stenosis was made, one had a mitral insufficiency, one had a pericarditis, and five had a systolic murmur In none was there any record of noteworthy cardiac decompensation

Since the group is too small to permit of any statistical observations a brief summary of eight cases has been included

CASE REPORTS

Case 1 Mrs A H, aged 40, came to the hospital with rheumatic fever of six weeks' duration She had been partially relieved by salicylates, but still had considerable pain, with swelling of the left knee and ankle There was a rather marked mitral stenosis well compensated She ran a low grade fever up to 101 degrees, the leukocyte count was 10,200 with 74 per cent granulocytes, 1 c c of blood settled

24 mm in 9 minutes. After her first fever treatment her pain subsided, fever lessened, and after five fever treatments of 104 to 105 degrees for three hours each she left the hospital in 21 days, pain and fever free, with 1 cc of blood settling 24 mm in 65 minutes. In the 19 months since dismissal this patient aside from a mild attack of pain one month later has been symptom free.

Case 2 Mr D W, aged 22, was admitted with a history that 12 days prior he had developed red painful joints following a severe sore throat. With large doses of salicylates he was improved but still had a swollen tender left knee, a low grade fever, a small area of consolidation at the base of the left lung posteriorly, and a pericardial friction rub heard best over the base of the heart. One cc of blood settled 24 mm in 23 minutes. He responded only slightly to bed rest and large doses of salicylates. After his first fever treatment he became pain free. He received three treatments of fever at 103 to 104 degrees for three hours each, and on dismissal was pain and fever free. The pericardial rub had disappeared and 1 cc of blood settled 24 mm in 70 minutes. Reexaminations during the following six months have shown no recurrences of symptoms. He has gained weight, the heart is normal in size by orthodiagraph and no murmurs are evident.

Case 3 G L McF, aged 14, was admitted to the hospital two days after developing swollen red knees. She gave a history of frequent sore throats. The present attack of rheumatic fever followed three weeks after a severe upper respiratory infection. She had fever up to 102 degrees, a mild hypochromic type of anemia with 13,400 leukocytes, 72 per cent of which were granulocytes. The sedimentation rate was 60 mm in 60 minutes. She had an early mitral stenosis and painful swollen knees. Two weeks of bed rest in the hospital and large doses of salicylates failed to produce improvement. She was then given fever treatments, receiving five at a temperature of 105 to 106 degrees for five hours each at intervals of approximately four days. Following her first treatment the swelling of the affected joints was markedly decreased and she was able to move her legs freely. After her fifth treatment the pain and joint swelling were completely gone. Her temperature and pulse were normal, the leukocyte count was 9,400 and her blood settled 43 mm in 60 minutes. On reexamination 2½ months later she had been entirely free of pain and fever, her joints were still normal, there was a marked improvement in the cardiac murmur. Electrocardiograph and roentgen-ray of the heart were also normal. Her leukocyte count at this time was 6,900 with 55 per cent leukocytes and her blood settled 18 mm in 60 minutes. This case showed marked improvement in contrast to previous failure with bed rest and salicylates.

Case 4 E L B, aged 40, with a history of a previous attack of inflammatory rheumatism 10 years ago, was admitted two weeks after the onset of the second attack, which involved in succession the left knee, left ankle and left foot. There were redness, swelling and limitation of movement. There was no evidence of heart involvement. His leukocyte count was 7,200, 55 per cent granulocytes, and the blood sedimentation rate was 18 mm in 90 minutes. The pain improved somewhat under rest and salicylates. A tonsillectomy brought no further improvement. Since the joint symptoms persisted fever therapy was tried, six treatments of four hours each at a temperature of 104 to 105 degrees, at weekly intervals. Following his fever treatment the pain and stiffness entirely disappeared and he gained six pounds in weight. He was entirely symptom free and without joint swelling 2½ months later.

Case 5 Dr C S, aged 26, had acute rheumatic fever twice, once nine years ago, and a recurrence eight weeks before entering the hospital. The left foot and both ankles were involved. After seven weeks in bed receiving salicylates he still had a tender swollen right wrist and swollen left foot. There was a definite systolic murmur transmitted to the axilla. The pulse was somewhat rapid and did not slow

down normally after exertion. His leukocyte count was 6,400 with 47 per cent granulocytes, and the blood sedimentation rate was 12 mm in 154 minutes. He was given two treatments of five hours each at 104 to 105 degrees at weekly intervals. Following these treatments the pain and swelling disappeared and he was able to return to his work as an intern. Five months later there had been no recurrence of symptoms. This case was relieved by fever therapy after failure following seven weeks of bed rest and salicylates.

Case 6 M A W, aged 11, school girl, with a first attack of rheumatic fever three years previously, entered the hospital one week after a recurrence. On admission she had a temperature of 102 degrees, a moderately advanced mitral stenosis, a leukocyte count of 11,600 with 87 per cent granulocytes, and blood sedimentation rate of 24 mm in 20 minutes. Both knees were red and swollen. Following three treatments of fever at 103 to 104 degrees for three hours each at four day intervals she became pain and fever free, her pulse became normal and her leukocyte count dropped to 9,800 with 58 per cent granulocytes and a blood sedimentation rate of 24 mm in 80 minutes. This patient felt well until two months later when, following an upper respiratory infection, she had a relapse. This relapse, treated by salicylates, bed rest and supportive measures, required four months to become inactive.

Case 7 B J, aged 9, entered the hospital with a chorea following an attack of acute rheumatic fever which began four months prior to entrance. He was running a low grade fever, there was a slight systolic murmur heard best over the apex and an occasional extra-systole. He received six treatments of fever at 102 to 103 degrees for 2½ hours at five day intervals. He made a rapid recovery. Examination eight months later showed no recurrence of symptoms and disappearance of the heart murmur. This patient entirely recovered from an attack of active rheumatic fever complicated by chorea.

Case 8 C C E, male, aged 48, entered the hospital with a history of painful and swollen joints for three weeks following an upper respiratory infection. The joints of the left arm, right arm and leg had been involved in succession. On admission he was unable to use the right arm or leg because of pain and swelling. The temperature varied from 98.6 to 104.4 degrees. There was a soft systolic murmur at the apex and the pulse was irregular at times. The liver was palpable one finger below the costal margin. His leukocyte count was 14,800 with 78 per cent granulocytes, and the blood sedimentation rate was 33 mm in 60 minutes. The electrocardiograph showed a low voltage in all leads. The heart was normal in size by roentgen-ray. He had had no previous attacks of rheumatic fever. There was improvement following large doses of salicylates and bed rest, but because of persistent joint manifestations he was given fever therapy, receiving five treatments at 105 to 106 degrees for five hours each at intervals of approximately four days. There was marked improvement at once in the joints and at the conclusion of the treatments pain, swelling and stiffness had disappeared. The temperature remained normal. The leukocyte count was 10,400 with 72 per cent granulocytes and his sedimentation rate was unaltered.

GENERAL COMMENT

Of the 15 cases treated by fever therapy, three were complicated by chorea. In the group 13 became symptom free following fever therapy. In all, three had relapses. E K had a slight attack of joint pain lasting a few days, two weeks after her last treatment. She then gained 30 pounds and was still symptom free seven months later. Second, M A W had a

relapse two months after completion of treatment which was purposely treated only with bed rest, supportive measures and salicylates. The attack lasted four months. Third, L. L. S., six months after treatment showed no murmur and no symptoms, but 21 months after treatment had a recurrence of chorea alone without leukocytosis, fever, or increased sedimentation rate. There is still no heart murmur and she is receiving further fever therapy at the present time.

One case (P. M.) showed moderate improvement although there were still rheumatic manifestations three months after fever therapy of 48 hours of fever between 103 to 105 degrees. This is the one case noted previously which showed residual joint damage.

Another case (W. M.) had essentially no improvement. After only 8½ hours of fever at 104 to 105 degrees, he refused further treatments. A tonsillectomy was also done without improvement.

Salicylates were given in 12 cases over periods of six days to seven weeks before fever therapy was tried. Although some relief was obtained, in no case was it complete.

Of the group three had tonsillectomies. One (W. M.) showed no benefit 10 days after tonsillectomy and is also recorded as a failure for fever therapy. Another (E. L. B.) received no relief within 10 days after tonsillectomy but did respond to fever therapy. The third case (M. B.) had received four treatments before the tonsillectomy, which was done as a prophylactic measure.

DISCUSSION

Our results indicate that fever therapy does produce definite symptomatic improvement, usually evident after the first treatment. The results obtained are commensurate with those obtained by Barnacle, Ewalt and Ebaugh¹ in chorea complicated by rheumatic carditis, and with our own unpublished observations in chorea. Sutton and Dodge² have reported five cases of rheumatic fever treated by mechanically induced fever with results similar to our own. In a recent personal communication from Barnacle, Ewalt and Ebaugh,³ the incidence of carditis in their 45 cases of chorea was 42.2 per cent, that is, 19 cases. Of these 19 cases, three showed evidence of mild decompensation and one had a pericardial effusion. Immediately following pyretotherapy seven cases of carditis were considered as recovered, seven were improved, and four unchanged. The case of pericardial effusion responded satisfactorily to fever, the effusion disappeared, and he is now in school and on full activity, 20 months after treatment. Of the 19 cases of carditis 12 have been carefully checked in recent follow-up examinations: six patients showed recovery and are on full activity program, while six are improved. There are other cases which are on full activity but the investigators were unable to check them personally so they

have not included these cases in their follow-up report. They have considered all of the accepted criteria for carditis in making their diagnosis and in arriving at the therapeutic results.

It is important, however, to recognize that individual attacks of rheumatic fever have a well marked tendency to subside spontaneously. On the other hand Bland and Jones⁴ in a study of 1,200 cases of rheumatic fever over a period of 13 years have stressed the persistence of low grade and sub-clinical infection with the periodic appearance of rheumatic manifestations. The tendency of rheumatic heart lesions to progress has been emphasized by many. Rothschild, Kugel and Gross⁵ and others have demonstrated the persistence of Aschoff bodies in cases of rheumatic fever as evidence of protracted activity.

It seems evident that fever therapy does reduce the symptomatic activity of rheumatic fever and probably shortens the duration of the attack. The more interesting point to us is whether or not fever therapy will aid in reducing the number of cases showing subclinical activity. In this connection the table shows that in many of the cases leukocyte counts and sedimentation times become normal after fever therapy. A final determination of this point will require much longer periods of study and a larger group of cases than are available to us at the present time.

The method of producing the fever in the patient is possibly not of great importance. Our experience with the Kettering hypertherm has impressed us with the nicety of control of the temperature and the ease with which the patient can be observed and treated while in the cabinet. In this connection it is interesting to note that Bland and Jones did not produce an activation of a rheumatic process in two cases following physical hyperthermia although activation was produced with typhoid vaccine. In the 15 treated cases in our group there is only one (E. K.) in whom such an activation might have recurred. This occurred two weeks after receiving the last of three treatments at weekly intervals. She received six hours of fever in all and the activation lasted two days. From our experience there would seem to be little danger of reactivating the symptoms.

SUMMARY

1 Fifteen cases of acute rheumatic fever were treated with the Kettering hypertherm cabinet for periods of 8½ to 46 hours with temperatures of 103 to 106 degrees.

2 Thirteen cases received complete relief from joint pain and swelling, three cases had recurrences within 2 weeks to 21 months.

3 The possible bearing of fever therapy on the subclinical activity of rheumatic fever is discussed.

4 Because of the uncertain course of acute rheumatic fever we believe that extended studies will be necessary before final evaluation is possible.

THE COURSE OF HYPERTENSIVE HEART DISEASE

III SIGNIFICANCE OF BUNDLE-BRANCH BLOCK

By NATHAN FLAXMAN, M D , *Chicago, Illinois*

BUNDLE-BRANCH BLOCK is not a frequent electrocardiographic finding Hill¹ reported 41 cases, the first 32 (0.8 per cent) of which occurred in a total of some 4000 consecutive cardiac cases examined electrocardiographically in the Royal Infirmary of Edinburgh White² stated that of 9000 cases with electrocardiograms at the Massachusetts General Hospital during 15 years there were 212 (2.35 per cent) with bundle-branch block During a period of one and one-half years at the Cook County Hospital there were 55 (3.34 per cent) cases of definite bundle-branch block in 1646 cases of organic heart disease³ These reports include cases due to all etiologic causes

This type of block occurs most commonly in patients over middle-age often the subjects of hypertension¹ The analysis of cases of bundle-branch block regardless of the etiologic cause of the underlying heart disease has been the method of choice, but is apparently as confusing as considering all the causes of auricular fibrillation under one heading to arrive at a common prognosis For this reason the present report includes only cases of uncomplicated hypertensive heart disease which showed electrocardiograms diagnostic of bundle-branch block Of the 786 uncomplicated cases of hypertensive heart disease seen over a five year period, 36 (4.58 per cent) had bundle-branch block as a constant electrocardiographic finding It was the next most common graphic abnormality after auricular fibrillation (26 per cent), but only one-sixth as frequent as this arrhythmia in the course of hypertensive heart disease Patients classified as having bundle-branch block had electrocardiograms which showed (1) definite left or right axis deviation, (2) appreciable slurring of the QRS complex with a measurable delay of over 0.1 second, and (3) T-waves pursuing a direction reversed from that of the major QRS complexes in Leads I and III All electrocardiograms showing marked delay and slurring of the QRS complex, but failing to fulfill the other criteria mentioned above, the heterogeneous group known as intraventricular, arborization, or incomplete bundle-branch block, were discarded As to whether to interpret the typical bundle-branch block under the old (classical) or the new terminology, this issue has been omitted My opinion, already expressed in previous writing,⁴ coincides with that of O'Farrell,⁵ who stated that it is doubtful from the clinical viewpoint if anything is to be gained by defining the location of lesions of the bundle with minute exactitude

* Received for publication March 27, 1937

From the Department of Medicine, Loyola University Medical School, Chicago

The age, sex, and race of the 36 patients in this series are noted in table 1. These data agree with all previous studies in that the majority were males (32 or 88.8 per cent) over 50 years of age.

* Bundle branch block in parentheses

compared with the general course of hypertensive heart disease where 85 per cent of the 170 deceased died within one year after the heart failure occurred ⁶

The duration of life after the detection of the bundle-branch block by graphic means was compared with the duration of life after the appearance of congestive heart failure (table 3, figures in parentheses, bundle-branch block) All of the 16 deceased patients died within 18 months after the block was recorded Herrick and Smith,⁸ in a report on 35 cases of bundle-branch block, stated that 12 or 57.1 per cent of 21 patients whom they were able to follow died within 18 months Cowan and Bramwell⁹ reported that 13 or 54.1 per cent of their 24 patients died within 18 months after the block was detected Sampson and Nagle¹⁰ noted especially the high fatality occurring in cases of bundle-branch block during the first year after the discovery of the lesion, and the remarkable diminution of the case fatality in the groups which survive the initial period Lewis¹¹ concluded that most of the patients who exhibit this lesion are dead within two years, but some

survive many years so that the prognostic significance of the sign itself is indecisive

There was a close and definite relationship between the congestive heart failure and the bundle-branch block in these patients. This association was first suggested by Cowan and Bramwell⁹ who stated that the presence of the block indicates a definite myocardial lesion, but if unaccompanied by signs of cardiac insufficiency is not necessarily of grave prognostic significance. Kurtz¹² reported six cases of transient bundle-branch block, all with organic heart disease, and in two he stated that it was closely associated with periods of myocardial failure.

TABLE IV
Percentage of Causes of Death in 16 Cases with Bundle Branch Block

| Causes of Death | White | | | | Colored | | | |
|-------------------------------------|-------|---|-------|-------|---------|---|-------|-------|
| | M | F | Total | % | M | F | Total | % |
| Congestive heart failure | 10 | 0 | 10 | 100.0 | 4 | 1 | 5 | 83.3 |
| Spontaneous rupture ascending aorta | 0 | 0 | 0 | 0.0 | 1 | 0 | 1 | 16.7 |
| Totals | 10 | 0 | 10 | 100.0 | 5 | 1 | 6 | 100.0 |

A survey of the causes of death (table 4) in these patients also brought out this relation of block to failure. Congestive heart failure was the cause of death in 15 (93 per cent) of the 16 deceased patients, all of whom died within 18 months after the onset of the failure and the graphic finding of the block. The exception was the youngest patient, a colored male of 31 years who was decompensated for the two years preceding his sudden death from a spontaneous rupture of the descending aorta. Analysis of the literature further bears out the relation of the heart failure to the bundle-branch block. Ten (83.3 per cent) of Herrick and Smith's⁸ 12 deceased patients died of cardiac failure. Nine (81.8 per cent) of Cowan and Bramwell's⁹ 11 deceased patients with hypertensive heart disease died of congestive heart failure. The important factor in these patients with hypertensive heart disease with bundle-branch block was the congestive failure and not the block, in spite of the fact that the graphic finding was typical and persistent in all cases. The importance of congestive heart failure in relation to hypertension and the heart has been emphasized on two previous occasions^{6, 13}

Those additional pathological findings which are common in hypertensive patients were found to be very infrequent in hypertensive cases with bundle-branch block. Gallop rhythm was present in five (13.8 per cent) of the 36 patients. All five were males, and 18 months after the detection of the bundle-branch block two were alive. Campbell and Suzman¹⁴ cited

the case of a 52-year-old male with cardiac symptoms of six weeks' duration and a blood pressure of 210 mm of Hg systolic and 130 diastolic, who had gallop rhythm and bundle-branch block. Nine months later the gallop and the block both had disappeared. They suggested that the gallop rhythm was due to the bundle-branch block, but my cases neither suggest nor bear out such a relationship.

Auricular fibrillation was present in only two (5.5 per cent) of the 36 patients, both white males, one white male (2.7 per cent) had a cerebral hemorrhage, and another (2.7 per cent) had a coronary occlusion during the course of the disease. Only one patient (2.7 per cent), a white female, had diabetes mellitus, which was of seven years' duration.

COMMENT

The pathogenesis of bundle-branch block in hypertensive heart disease is indefinite. In an extended review of the literature Rosenthal¹⁵ found no discussion of this topic. From his studies he concluded that the degenerative changes which occur in the bundle are explained by an increased tonicity of the small arteries and the arterioles which brings about prestasis and stasis in the precapillaries and capillaries.

There are probably many examples of longevity with bundle-branch block which have not been reported. The Bishops¹⁶ cited the case of a 47 year old woman with a blood pressure of 200 systolic and 105 diastolic who had dyspnea of one year's duration when the block was first recorded. Eleven years later she was still well and still showed the bundle-branch block. Sampson and Nagle¹⁰ reported one patient still in reasonably good health 12 years after the discovery of the lesion. In the present series one woman was alive 10 years after the block was noted.

SUMMARY

Bundle-branch block, graphically noted in the course of hypertensive heart disease, occurred in 36 (4.58 per cent) of 786 patients with this disease. It appeared to have no definite diagnostic or prognostic significance in these patients. The block was considered as only an unusual electrocardiographic finding in hypertensive heart disease, the mechanism of which was not clear. The prognosis of the hypertensive patient with bundle-branch block was that of the underlying heart condition, particularly in relation to the occurrence of congestive failure. Sixteen (44.4 per cent) of the patients died within 18 months after the bundle-branch block was graphically noted, and in all except one the cause of death was the congestive heart failure. There was a very close relationship between the bundle-branch block and the congestive heart failure in the insufficient hypertensive heart.

THE ASSOCIATION OF ADENO-MYO-SARCOMA OF THE KIDNEY (WILMS TUMOR) WITH ARTERIAL HYPERTENSION *

By J EDMUND BRADLEY, M D , and M C PINCOFFS, M D , F A C P ,
Baltimore, Maryland

THE rôle played by disease of the kidneys in the pathogenesis of arterial hypertension has always enlisted the interest of clinicians. Bright drew attention to the fact that in cases of albuminuria there was frequently found hypertrophy of the heart. Traube and Cohnheim correctly interpreted the cardiac hypertrophy as due to increased blood pressure. The association of arterial hypertension with Bright's disease was thus early established. The nature of the relationship was variously interpreted, but the most widely accepted viewpoint was that the disease of the kidney was primary and that from it arose unknown consequences that brought about an abnormal elevation of the blood pressure.

With the gradual differentiation as an entity of essential hypertension or hyperpiesia, and the acceptance of the fact that in this disease the elevation of blood pressure precedes often by years any detectable renal lesion, a first important step was taken away from the conception of an exclusively renal etiology of high blood pressure. There remained, however, as firmly founded, the relatively constant association of acute and chronic glomerulonephritis with arterial hypertension. The most commonly accepted explanation of this association still is that the kidney damage is the primary event and that the arterial hypertension is secondary. On the other hand, in the last 15 years an important group of investigators of this problem have put forward the hypothesis that the disease which we call glomerulonephritis is in fact a diffuse vascular disease characterized by angiospasm. The arterial hypertension according to this theory is a consequence of widespread arteriolar and capillary constriction due to vascular disease. The renal lesions are likewise a product of vascular disease in the kidney, ischemic according to some authors, or primarily due to damage to glomerular capillaries according to others. Those who have accepted this point of view are therefore of the opinion that the kidney lesions are secondary, both in essential hypertension and in glomerulonephritis, and that in neither condition is kidney damage an essential factor in the pathogenesis of the accompanying hypertension. The more radical opponents of any renal origin of hypertension will not even concede that the kidney damage in such conditions as chronic pyelonephritis and polycystic kidneys gives rise to the arterial hypertension which accompanies these conditions in a significant percentage of the cases.

* Read in part before the Association of American Physicians, Atlantic City, May 1937.
From the Departments of Pediatrics and Medicine, University of Maryland School of Medicine.

Such extreme opinions are no longer tenable in view of the developments of the last few years. The earlier failures to produce arterial hypertension experimentally in animals by various types of induced kidney damage have been followed by the development of successful methods. Of these the most dependable is that of Goldblatt¹ which consists essentially of a partial occlusion of the renal arteries by means of special clamps. The elevation of the blood pressure in such animals is of marked degree and may be sustained over months or even years. The removal of the clamps in the earlier stages of the process will result in the subsidence of the blood pressure to normal levels. The well controlled work of Goldblatt has definitely shown that in animals this type of interference with the blood supply of the kidneys will produce an arterial hypertension. Moreover recent careful studies of large series of cases of polycystic kidney and of chronic pyelonephritis have definitely shown that an abnormally elevated blood pressure accompanies these conditions at all ages in a percentage of cases too large to be due to coincidence. Further, in autopsied cases of these conditions no cause for the hypertension, other than the renal lesions, has been found. Since the incidence of the hypertension, especially in the early age groups, is too high to be explainable as a coincidental occurrence of so-called essential hypertension, these studies point strongly towards a renal causation for the hypertension in these primarily renal diseases. However, since the lesions are bilateral there is no opportunity to obtain further evidence through observation of the effects on the arterial hypertension of the surgical removal of the presumably causative lesion.

The existence of a renal form of hypertension in man might be considered finally proved if a renal lesion were discovered in man, whose presence was constantly associated with arterial hypertension and whose surgical removal constantly led to the fall of this pressure to normal levels. In five consecutive cases, in infants and young children of the so-called embryonal adeno-myo-sarcoma of the kidney (Wilms tumor) we have observed the concurrence of arterial hypertension. In two of these cases we were able to observe the effect of operative removal of the tumor and found in each that a marked lowering of the blood pressure occurred and that with recurrence of the growth the blood pressure again rose to higher levels. These observations suggest that through a study of a more extensive series of such cases important evidence as to the existence and the nature of human renal hypertension may be obtained. For this reason the data on these cases are felt worthy of report.

CASE REPORTS

Case 1 J. C., a white female child, aged two years, was admitted to the University Hospital because of a mass in the right abdomen, noted first nine days previously and because of hematuria of 24 hours' duration. The history otherwise was of no significance. On examination the mass was found to fill the right abdomen from the costal margin to the iliac crest. It caused a visible protrusion of the abdominal wall. An intravenous pyelogram showed no filling on the right side.

The blood pressure of this child (figure 1) and of the later cases was determined with a mercury manometer with a 3 inch cuff with due care to record only pressures taken when the child was quiet. Blood pressures are taken routinely on the pediatric service. A pressure of 90 mm systolic and 60 diastolic is considered normal for this age.^{2, 3, 4}

This child's pressure before operation was between 150 mm and 180 mm systolic and the diastolic was consistently over 110 mm. The consistency of the elevation of the pressure is noteworthy. Frequent readings throughout the day were taken but no evidence of abrupt variations nor of paroxysmal elevations was obtained.

Study of the renal function showed a two hour phthalein excretion of 80 per cent the specific gravity in the Mosenthal test ranged between 1.018 and 1.032 the non-protein nitrogen was 21 mg per cent. The hypertension, therefore, bore no relation to faulty renal excretory function.

The heart on physical examination and by teleoroentgenogram was not enlarged and the sounds were normal. The electrocardiogram, however, showed left axis deviation and a deep Q. The retinal arteries showed no change.

Nineteen days after admission an attempt was made to remove the tumor surgically. The greater part of the encapsulated mass occupying the site of the right kidney was taken out, but because of the friability of the tissue and the bleeding encountered a portion had to be left. Within a few days after operation the child showed definite improvement. She was alert, interested in her playthings and took nourishment with good appetite. This period of clinical improvement lasted somewhat over two weeks. Then she began to drift down hill. Palpable evidence of

BLOOD PRESSURE CHART

FIG 1 Blood pressure chart in Case 1

recurrence was noted at the end of the third week and by the time death occurred from cachexia and bronchopneumonia, three months after operation, the right abdomen was again filled with a large mass. It may be seen on the chart (figure 1) that following operation during the period of clinical betterment the blood pressure was distinctly lowered, falling to 130 systolic and 100 diastolic, but that as the tumor again increased in size the blood pressure gradually rose and reached its former high level, in a period when the child exhibited marked emaciation and weakness.

The tumor tissue removed at operation weighed 500 gm. Sections (figure 2)

showed numerous epithelial elements arranged in tubular, cystic and glomerulus like structures, embedded in a matrix of myxomatous and spindle cell connective tissue. Muscle fibers were noted in frozen sections. The tumor tissue was very vascular. Large areas of necrosis and of hemorrhagic infiltration were observed. The pathological diagnosis was "A typical embryonal adeno-myo-sarcoma, or Wilms tumor."

FIG 2 Section from tumor mass in Case 1

In an attempt to discover the nature of the pressor action of the tumor, gross serial sections of the mass were carefully studied and numerous blocks taken and sectioned to see whether adrenal medullary or cortical tissue or aberrant chromaffine cells were present. None was found. Moreover, immediate extraction of two samples of fresh tumor tissue was carried out by Dr Wm H Schultz. The pressor effects of these extracts on intravenous injection were tested in young dogs and found to be nil. The extracts gave no color reactions for adrenalin and no adrenalin reaction on intestinal or virginal uterus muscle strip preparations.

An autopsy of this patient showed a massive tumor recurrence weighing 1860 gm. The left kidney and both adrenals were found normal grossly and microscopically. The heart weighed 50 gm which is normal for this age. The larger arteries showed no gross evidence of arteriosclerosis.

Case 2 B C, a colored male child, aged two years, was admitted to the University Hospital in May 1935, because of hematuria of 48 hours' duration. The past history contained nothing significant aside from rather numerous respiratory infections. The child was normally developed for the age. On palpation of the abdomen a globular mass was felt on the right side extending from the costal margin to the crest of the ilium. An intravenous pyelogram showed marked dilatation of the pelvis and calyces of the greatly enlarged right kidney. For four days after admission the patient had a severe hematuria with a considerable total loss of blood.

This child's systolic pressure varied between 120 and 140 mm and the diastolic between 80 and 100 mm (figure 3). This is a well marked though not severe hypertension, when one considers that a pressure of 90 systolic and 60 diastolic is normal.

for this age period This elevation of blood pressure was continuous during the month preceding operation

As in the first child there was no evidence of depression of renal function The phthalein output in two hours on two tests was 65 per cent and 80 per cent The non-protein nitrogen was 26 mg per cent A range of specific gravity between 1 012 and 1 028 was noted

The physical examination of the heart and the teleoroentgenogram did not give evidence of any cardiac enlargement The electrocardiogram did not show left axis deviation and was otherwise also quite normal The retinal arteries showed no changes

FIG 3 Blood pressure chart in Case 2

One month after admission an operation was performed, a large encapsulated tumor arising from the right kidney was found Kidney and tumor were removed *in toto* (figure 4) The child stood the operation very well, the post-operative healing was uneventful and the child was discharged from the hospital 15 days later Thereafter the patient was seen at intervals in the out-patient department over a period of seven months The blood pressure was normal, 88 systolic and 60 diastolic, until in the sixth month when it began to rise and in the seventh month again reached its former hypertensive level At this last visit a palpable mass was noted at the site of the former tumor Unfortunately, the parents refused to return the child to the hospital, moreover they moved their residence and all attempts to trace this case further were fruitless

The tumor removed at operation from this case was a globular mass replacing the middle section of the right kidney The growth was made up of rather uniform oval or spindle cells, without bundling, but instead rather indiscriminately scattered through a fibrous stroma Hyalinized areas were observed, vascularity was not a prominent feature Only scant adenomatous structures were noted The pathological diagnosis was "A fibrosarcomatous variant of the Wilms tumor"

Case 3 R R, a white male infant, aged two months, was admitted to the Mercy Hospital with the history of increasing abdominal enlargement for one month

FIG 4 Right kidney containing tumor from Case 2

FIG 5 Blood pressure chart in Case 3 The heavy black line indicates the period of roentgen-ray treatment

The child showed marked malnutrition and the greater part of the abdomen was occupied by a large firm mass. The presence of a few red blood cells in the urine and the lack of filling of the right pelvis and ureter on intravenous pyelography indicated that the mass arose from the right kidney.

Sixteen days after admission, through the kindness of Dr. Edgar Friedenwald, one of us was enabled to begin determinations of this child's blood pressure (figure 5). It was found to range between 106 and 116 mm of Hg systolic and between 85 and 90 mm diastolic. The normal mean pressure for this age as determined

FIG 6 Blood pressure chart in Case 4

in a series of cases (by J. E. B.) is 78 systolic and 56 diastolic. Hence this child's pressure in spite of its cachectic state was elevated to a level corresponding to 150 systolic and 100 diastolic in an adult. The level of the pressure was not affected by a period of irradiation of the growth which very greatly reduced its size. This treatment together with small transfusions was given in preparation for operation but three months after admission the infant was carried off by an acute diarrhea.

At autopsy the remaining mass weighed only 110 gm. The right kidney was almost completely destroyed. The tumor tissue showed marked necrosis, cystic

degeneration and hemorrhagic infiltration. The microscopic sections showed sparse epithelial tubular-like structures in a stroma of spindle cells and myxomatous tissue. The left kidney and both adrenals were normal.

Case 4 J R, a white female child, aged two years, was admitted to the Maryland General Hospital in November 1936, because of a painless enlargement of the abdomen of six weeks' duration. On examination a large nodular mass was found occupying most of the left half of the abdomen. An intravenous pyelogram showed no visualization of the left kidney pelvis. The urine examinations were negative. The non-protein nitrogen was 22 mg per cent. Operation revealed a large tumor of the left kidney which had broken through its capsule in several places. This was removed. Recovery was uneventful. Five months later the patient was readmitted with a large palpable recurrent mass. At this time through the kindness of Dr R P Bay, one of us was able to make repeated determinations of the blood pressure (figure 6). These showed that the systolic pressure ranged consistently between 140 and 150 mm of Hg and the diastolic between 100 and 112 mm.

FIG 7 Blood pressure chart in Case 5

The tumor from this patient was partly cystic and partly solid. A gelatinous tissue occupied the cystic area. The more solid tissue contained numerous epithelial elements surrounded by a fibromuscular stroma very characteristic of embryonal adeno-myo-sarcoma or Wilms tumor.

Case 5 M H, a colored male child, six years of age, was admitted to the University Hospital on January 5, 1937 with a complaint of enlargement of the abdomen which had been first noted approximately one year earlier. During this interval vague complaints of abdominal pain of no definite type had been made. Within the two months prior to hospitalization, the abdomen had greatly increased in size. It was stated that constipation had been present since birth and that the child had suffered with occasional respiratory infections. Otherwise the history contained nothing of interest.

On examination the child was well nourished. A mass was palpable in the left flank extending to slightly beyond the midline medially and from the costal margin above, downward almost to the crest of the ileum. It was globular, hard, freely movable, non-sensitive and of even consistency. The edge of the liver extended two fingers-breadth below the costal margin in the nipple line. Both intravenous and

retrograde pyelography failed to show any filling of the left kidney pelvis. The right ureter and kidney pelvis were normal in outline. A clinical impression was that the tumor arose from the left kidney and was probably a Wilms tumor.

The blood pressure in this child on admission was 160 systolic and 124 diastolic (figure 7). The pressure remained consistently elevated throughout the five months' stay of the patient in the hospital. As terminal cachexia set in there was an appreciable decrease in both systolic and diastolic pressures, but, as may be seen from the blood pressure chart, neither ever attained normal levels. The steadiness of the blood pressure level was rather striking for a child of this age. On one occasion readings were made every two hours for sixteen hours (figure 8) and showed very slight variations.

Very numerous urinary examinations in this patient's case failed to show any abnormalities. Concentration tests showed a range of specific gravity between 1.024 and 1.030 on one test and of 1.012 and 1.023 on a second test. The urea clearance was 80 to 87 per cent. The phthalein output was 70 per cent in two hours, the non-protein nitrogen 24 to 32 mg per cent.

Examination of the heart showed clinically no evidence of enlargement, nor change in the rhythm or character of the heart sounds. The electrocardiogram was reported as normal and the teleoroentgenogram showed a normal cardiac outline. The examination of the ocular fundi on admission did not show any vascular changes, but later in the patient's course it was noted that there was some increased tortuosity of the arteries and an increase of the light reflex.

For a period of six weeks after admission the child was treated with roentgen irradiation of the tumor. Nevertheless, during this time the liver increased markedly in size, extending downward into the right flank. The left eye began to show proptosis and vision in this eye was lost. These changes were taken to indicate metastatic growths in the liver and in the left orbit. Roentgen-ray of the skull did not show any bone metastases.

An exploratory laparotomy now revealed a very vascular mass involving the left kidney region and extending across the midline to blend with an ill-defined growth apparently invading both the liver and the right kidney. No tumor tissue was removed.

The subsequent course was entirely downhill with increasing cachexia, increasing enlargement of the abdomen and extension of the orbital metastases downward into the nasal cavity. The child died 151 days after admission. Because of the interest attached to the widespread metastases in this case, complete autopsy findings are appended.

Autopsy June 3, 1937. Pathologist Dr. M. S. Sacks. The body is that of a young negro male child measuring 105 cm in length. It is markedly emaciated. The head and scalp show no changes. There is marked proptosis of the left eyeball. The right eye shows no changes. Examination of the mouth reveals a small cauliflower-like lesion in the hard palate which measures approximately 1 cm in diameter. The chest is emaciated and the abdomen is markedly distended. There is a partially healed left paramedian incision. The external genitalia reveal no change. There is no external lymphadenopathy, jaundice or edema.

The subcutaneous tissue is practically devoid of fat. The musculature of the thorax and abdomen is pale, thin and flabby. On opening the peritoneal cavity there is a gush of clear yellow serous fluid. This is present to the extent of about 200 cc. The liver is seen to occupy almost the entire upper half of the abdomen. It extends down for a distance of 12 cm below the right midclavicular line. There is a second mass noted in the left flank and as a result of the presence of these masses the entire gastrointestinal tract is pushed downward to the right.

The anterior chest plate is removed and both pleural cavities are seen to be free of fluid or adhesions. The pericardium is smooth and glistening but is somewhat

FIG 8 A two-hourly blood pressure chart in Case 5

distended by an excess of clear yellowish serous fluid. The thymus is quite small, it occupies its usual position and reveals no gross changes.

Heart. Weight 110 grams. The epicardium is smooth and glistening. The heart appears to be of normal size. There is some dilatation of the right ventricular cavity. The myocardium has a homogeneous pinkish gray appearance and presents

no gross pathologic change The endocardium both mural and valvular shows no change

Aorta The aorta is small—of normal caliber, very elastic and presents no intimal changes

Lungs Right weighs 250 grams—left 200 grams Both lungs are removed together with the trachea The trachea is patent throughout and examination of its mucosa reveals no pertinent changes The tracheobronchial lymph nodes are found somewhat enlarged, these have a dark red, almost hemorrhagic appearance, they are soft and measure up to 2 cm in length Left lung Examination of the pleural surface reveals it to be glistening but to be studded by multiple nodules of varying size, some of which are sessile and some pedunculated These nodules vary in size up to 5 cm in diameter They are soft and have a pinkish red appearance Some have a distinctly cauliflower-like appearance They are found on all surfaces of the lung On cross section all lobes have a pinkish gray dry appearance and numerous nodules are noted projecting from the cut surface The lobes are distinctly less crepitant than normal The right lung presents an essentially similar appearance One nodule on the pleura of the right lung has a multilocular cystic appearance On puncturing these cysts they are seen to contain air

Liver This organ is tremendously enlarged and weighs 2,700 grams Its contours are markedly distorted by the presence of numerous, roughly circular, metastatic nodules measuring up to 7 cm in diameter These nodules are soft, have a yellowish gray color, with thin red streaks running through them, which tends to give them the appearance of the cut surface of an orange On section it is noted that these masses have displaced the vast majority of the parenchymal cells They have a similar appearance on cut surface The gall-bladder and biliary passages present no gross pathologic change

Kidneys Right weighs 110 grams—left 1,000 grams Right kidney This organ has been markedly compressed and flattened in its anteroposterior diameter by the overlying markedly enlarged liver It can be readily separated from the overlying liver The capsule strips with ease revealing a pale grayish-red smooth surface On cross-section the architecture is seen to be very indistinct The calyces and pelvis are of normal size—smooth and glistening—and show no changes The ureter is patent throughout and of normal size

Left kidney This kidney measures 18 by 12.5 by 7 cm The greater part of the kidney parenchyma has been replaced by a large firm grayish yellow tumor mass At the lower pole may be distinguished a small fragment of pinkish red tissue which bears a resemblance to normal tissue The entire tumor mass and kidney are covered by a dense grayish white capsule The ureter, which is of normal size, may be seen entering at the lower pole of this mass On cross section the cut surface of the tumor has a somewhat lobulated, yellowish-gray, moderately firm appearance At the extreme lower pole may be noted a section of recognizable kidney parenchyma

Adrenals The adrenals occupy their normal position but both are markedly flattened out The right adrenal on section possesses a definitely recognizable cortex and medulla The left adrenal can be separated with ease from the underlying kidney tumor mass and it possesses a grayish-brown homogeneous appearance on cut section, without distinguishable cortex and medulla

Bladder The bladder is small, contracted, empty Examination of its mucosa reveals it to be smooth, gray and glistening

Spleen Weight 70 grams It is firm, the capsule is smooth and taut On section the pulp is dark red The Malpighian bodies may be readily distinguished

Pancreas Weight 30 grams There is no external abnormality and cross section reveals no change from normal

Gastrointestinal Tract The esophagus is patent throughout and reveals no changes. The stomach is contracted. The rugae are prominent but no gross lesions are evident. Examination of the mucosa and wall of the remainder of the intestinal tract reveals no changes until one comes to the descending colon. The wall here is somewhat thicker than normal. The mucosa has an edematous appearance and under the serosa may be noted multiple small petechia-like areas occurring in large numbers.

Lymph Nodes The peripancreatic lymph nodes display a red hemorrhagic appearance, they are somewhat larger than normal. On cross section they present a red granular surface.

Head Not opened.

Anatomical Diagnosis

Embryoma (Wilms tumor) left kidney, with metastases to liver, lungs, parietal and visceral pleurae, palate, left orbit, peri-pancreatic and tracheo-bronchial lymph nodes, proptosis, left eyeball, ascites (200 cc), pulmonary atelectasis, partial, bilateral, partially healed left para-median surgical incision, emaciation, extreme

Microscopic Notes

Heart This section of left ventricular myocardium shows well preserved muscle fibers which are apparently moderately hypertrophied. The epicardium is seen to contain a moderate amount of fat. Cross sections of coronary vessels seen here show no thickening of their walls. There is no scarring or increase in interstitial tissue.

Lungs (two sections) These sections show an air containing tissue. Occasional groups of alveoli are collapsed but these seem to be in proximity to tumor nodules. The interalveolar capillaries are congested. The bronchioles are normal histologically. Scattered throughout the parenchyma and also arising from the visceral layer of pleura are noted fairly numerous nodules composed of neoplastic tissue. The nodules are of varying sizes and display a structure which varies from a densely cellular compact tissue to one composed of loose, anastomosing cords of cells. These nodules are extremely vascular and are composed of cells possessing no distinct cytoplasmic boundaries, which have a small, somewhat vesicular oval nucleus. Such cells form wavy strands of tissue intermingling in all directions. No distinct epithelial elements are present. A very scant, underlying acidophilic stroma is noted in some areas.

Liver Three sections are examined. One shows the uninvolved parenchyma and the other two are portions of the large metastatic nodules. The parenchyma proper displays no disturbances of architecture. The liver cords are perhaps somewhat compressed and there is slight congestion of the central venules. Scattered cells show mild fatty changes. The tumor nodules have a distinctive structure. One sees here narrow, anastomosing bands of cells, with elongated spindle-shaped nuclei often displaying a prominent nucleolus. These bands are separated from each other by a pale, relatively acellular, loose alveolar-like type of tissue. The nodules are quite vascular. They have apparently compressed and destroyed the liver parenchyma previously present.

Spleen This section shows a cellular pulp which is moderately congested. The venous sinuses are patent. Malpighian bodies are numerous and of normal appearance. Some display germinal follicles. No evidences of neoplasm noted.

Pancreas This section reveals evidence of moderate postmortem autolysis affecting the acinar and islet epithelium. No vascular wall thickening is present.

Large Intestine This section shows a well preserved mucosa and no histological changes in the other layers. Several arterioles are observed in the mesentery and none of these shows any marked intimal thickening.

Kidney (a) Left—This section reveals no disturbance of the normal architectural patterns. The glomeruli are numerous. Epithelium of convoluted tubules shows moderate swelling and some granularity of the cytoplasm. No interstitial changes are present. The arterioles display no changes.

(b) Right—This section displays a narrow peripheral strip of kidney parenchyma with several processes extending downward into a tumor mass. The glomeruli are small and compressed and there is a marked increase in interstitial fibrous tissue. Many tubules are obliterated and those remaining are narrowed and compressed. The tumor boundary is well defined. The neoplasm itself shows an abundance of relatively cellular fibrous tissue between the bundles of which are narrow strands of hyperchromatic cells of a similar appearance to those described above. No epithelial elements are present here and the striking thing is the abundance of fibrous tissue.

Adrenals Three sections are studied, representing portions of both adrenals. These sections reveal narrowing of the entire gland which is particularly marked on the left. The narrowing results in giving the glands an appearance of being all cortex. Moderate postmortem autolysis is noted. Several small cortical adenomas are present. No evidence of neoplastic change present.

Lymph Nodes Three sections examined. One displays no neoplastic involvement, but instead shows a markedly congested medullary portion (probably peripancreatic in location). In the other sections neoplastic tissue, chiefly fibrous in nature, has invaded the glandular structure.

ASSAY OF TUMOR TISSUE

Through the kindness of Dr. John C. Krantz, Jr., of the Department of Pharmacology, the following studies were made to determine the presence of adrenaline or of any other pressor substance in the tumor tissue.

Twenty-five grams of fresh tissue representing different portions of the tumor were finely minced, agitated briskly for one-half hour with 100 cc of normal salt solution, strained and centrifuged. The faintly opalescent liquid obtained gave a positive test for adrenaline with the Folin-Cannon-Denis reagent. The intensity of blue corresponded to about a 1×10^{-5} adrenaline. This reaction is not specific for adrenaline. The Vulpian reaction (FeCl_3 , green color—specific for catechol derivatives) was negative. Comessatti reaction (pink with sodium acetate and mercuric chloride) was negative.

Dog—light ether anesthesia—normal carotid B P 150 mm Hg

| | | |
|------------------|------------------------|-------------------|
| Injectons 0.5 cc | $1-10^{-4}$ adrenaline | 20 mm rise in B P |
| 10 cc | $1-10^{-5}$ adrenaline | 4 mm rise in B P |
| 10 cc | tumor extract | no change |
| 20 cc | tumor extract | no change |
| 50 cc | tumor extract | no change |
| 50 cc | tumor extract | no change |
| 50 cc | tumor extract | no change |

The dog's B P was still sensitive to adrenaline

Ten cc of the extract were shaken briskly with activated charcoal (adsorption of histamine, adenosine, adenylic acid and other depressors). The filtrate (5 cc) was twice injected into the same dog—there was no rise in blood pressure.

The animal experiment along with the negative chemical tests indicate the absence of adrenaline in the tumor, and of any pressor substance extractible by slightly acidulated saline solution.

DISCUSSION

The kidney is the most frequent site of neoplastic disease in infancy and childhood^{5,6} and tumors of the kidney account for approximately 25

per cent of all the malignant growths occurring in this period. The commonest renal tumor at this age is a mixed tumor, named from its structure embryonal adeno-myo-sarcoma, but also frequently designated as the Wilms' tumor. Mixer,⁷ in computing the frequency of this tumor, found 41 renal growths in 22,000 admissions to the Children's Hospital in Boston, of which 30 were of the Wilms type. These tumors are, as a rule, encapsulated, oval to globular in shape, solid and variously subdivided into lobules. The tumor formation is usually separated by a layer of fibrous tissue from what is left of the kidney in which it has developed. The kidney tissue is usually atrophied to a greater or lesser extent by pressure but otherwise shows no abnormalities. Microscopically the growths are composed of so many different types of tissue and exhibit such different degrees of differentiation that no single morphological description will apply. In general, it may be stated that they are composed of a mixture of tissues in which are found nonstriated muscle, fibrous and myxomatous connective tissue and complex arrangements of epithelium suggesting glomeruli and tubules. Adipose tissue and cartilage may also be found. The origin of the tumor is undoubtedly from fetal rests. Wilms, Birch-Hirschfeld, Busse, Ewing and others have offered various theories as to their origin, the only resultant agreement being as to the embryonic nature. The tumor is essentially malignant, metastases occurring mainly by the blood stream and usually affecting the liver and lungs, rarely the opposite kidney. Widespread metastases, such as occurred in M. H. (Case 5), are unusual. Since the growth of these tumors is usually asymptomatic, they are, as a rule, quite large when diagnosed. Therapy by irradiation followed by operation is recommended but rarely results in cure.

We have not found in the literature any earlier observations upon the association of arterial hypertension with embryonal adeno-myo-sarcoma. We do not, of course, feel that the constancy of this association can be considered established until a large series of cases has been observed. It seems important that this fact be determined for if the association is a constant one it will become more likely that the tumor tissue itself is the cause of the hypertension, whereas if hypertension is found in only a certain percentage of cases with Wilms' tumor, as is the case in the hypertension of polycystic kidneys, pyelonephritis and urinary back pressure, it will appear more likely that its cause must be sought in some occasional complication of the tumor growth such as disturbances in its arterial supply, necrosis of tumor tissue, etc. Our own endeavors to find a pressor substance in the tumor tissue or the inclusion within it of aberrant chromaffine tissue have given negative results.

The question arises whether the hypertension might be due in these cases to the kidney tissue damaged by pressure from the tumor growth rather than by the tumor tissue itself. In our second case, B. C., the entire kidney

containing the growing tumor was removed surgically (figure 4), nevertheless, the recurrent growth of tumor tissue led to a return of the hypertensive state

That the hypertension in these cases was in some way a consequence of the tumor growth seems to us a reasonable conclusion from the facts presented. In the first place, the possibility that the association of the two conditions was an accidental one must be considered very remote. Hypertension in infancy^{8, 9, 10, 11} is quite a rarity and when found has usually been accompanied by glomerulonephritis or chronic pyelonephritis or in isolated cases by adrenal medullary tumors, brain tumors or coarctation of the aorta. In our cases, no evidence of nephritis was present in life, renal function was unimpaired and in three cases at autopsy the remaining kidney was histologically normal. In these three autopsied cases likewise the adrenals showed no abnormality. There was no evidence of urinary back pressure. In two cases the aorta was examined and found normal. There was no evidence to suggest an intracranial lesion. In brief, then, complete examination in three cases and such data as we possess on the other two do not afford any other explanation than the tumor for the hypertension.

Moreover, in two cases the removal of the tumor was followed by a significant fall in blood pressure. In the second case, in which the removal was apparently complete, the blood pressure fell to normal levels and remained there for some months. Finally in both of these cases recurrence of the tumor growth was accompanied by a return of the hypertensive state.

It is of particular interest, we feel, that a unilateral renal lesion should cause elevation of blood pressure. In experimental hypertension a permanent elevation has rarely been obtained except when both kidneys have been damaged. It is of interest also that the level of the elevated blood pressure is quite steadily maintained.

We feel that the tumor tissue in these renal tumors has a property possessed by renal tissue when it has been altered by certain types of damage—that is, the property of causing, through as yet unknown mechanisms, an abnormal elevation of arterial pressure. These observations of the relation of these renal tumors to hypertension furnish new support to the view that there are clinical forms of high blood pressure of primary renal causation.

MEDICAL SHRINES

Remarks at the Annual Banquet of the American College of Physicians
1937

By LOGAN CLENDENING, M D , F A C P , *Kansas City, Missouri*

TONIGHT it is my purpose to discuss with you some memories of our past—the past of medical science and of medical service. Specifically, I want to discuss the memorials of the men and institutions that made that past—memorials in the form of hospital or university buildings, or in the form of statues of the great men and women of our tradition, their birth houses appropriately marked, or their graves properly inscribed.

And I want to suggest that it is a function of this College to encourage the memorialization of our American medical shrines. In our restless and changing country the dwellings and haunts of our pioneer physicians disappear, and all relics and reminiscences of them become scattered or lost. Do we not owe it to them at least to collect their records while those who can recall the past are still here to help us?

Do not be alarmed! I do not intend to desecrate the post-prandial ruminative mood which sits so becomingly on your genial countenances, my learned fellows, by suggesting a subscription. All I ask is your moral support of the work of the local profession, whose duty it should be to do this work in each community. And moral support is a commodity easy to donate, even in the after-dinner glow.

For the past decade and a half, I have spent a considerable portion of my life wandering over the face of the earth seeking out and studying these memorials. They are not always easy to find. They are not usually regular objects of sightseeing, nor frequently given prominence in the guide books. Statues of generals and kings and lawyers there are, as you know, aplenty. Physicians and scientists are hard to find. But there comes a peculiar satisfaction when you do find one. It is possible for mankind to remember gratefully the events that really contributed to civilization as well as battles.

For instance, I was walking a year or two ago in the majestic old eighteenth century city of Bath, around the Circus that once was and still is a fashionable crescent of residences. I had noticed a small plate affixed to one door which announced that this house was once the residence of Richard Brinsley Sheridan, so I became interested in reading these notices. Suddenly I found myself peering at a silver plate which marked the home of Caleb Hillier Parry, 1756–1822. How many visitors to that Athens of the West would know of the achievements of “the distinguished old Bath physician,” as Osler called him, he who described the combination of

* Read at the St. Louis Meeting of the American College of Physicians, April 22, 1937

exophthalmos, goiter and tachycardia, he who was the friend of Jenner, to whom the *Inquiry* is dedicated? And yet to those of us who do know the man, the thought that someone had the pride and took the trouble to point out his earthly residence, is moving and warming

Various communities differ somewhat in their feelings towards their illustrious dead. Last year I determined to visit Berkeley in Gloucestershire, the birthplace and the scene of the labors of Edward Jenner. We established ourselves at Bath as headquarters for the trip and the word "established" bid fair to be very accurate. We were greeted on our first day with a steady, grim downpour of rain. And such wet rain—you could hardly cross the street without being drenched. We stayed in our room with a fire of channel coal (sixpence extra a day) and we stayed there for several days while the weather gave an example of what it could really do to be nasty. At last a morning of semi-sunshine gulled us into taking the bus for Bristol. A fine drizzle greeted my attempts to find the birth house of Richard Bright, and by the time we had seated ourselves in the Gloucester bus the landscape was awash again. At Berkeley it did threaten to clear and remembering the traditions of the excellent cuisine enjoyed by that convivial medical society of which Jenner was the moving spirit when it met at the Berkeley Arms, I ordered lunch and inquired the way to the local mementoes of Jenner. The landlady looked blank and asked me to repeat the name. I did so, adding the information that he had introduced vaccination against smallpox. She said she thought he was dead. I replied that I feared so, too, but would like to see his grave, or statue, or house. She said she didn't hold with vaccination herself but there was a stable boy who specialized in such matters.

While I awaited the arrival of the learned stable boy, I asked for a guide book. A pamphlet on Berkeley was procured, most of the contents of which were devoted to a description of Berkeley Castle, the seat of the Earls of Berkeley, and the principal distinction of which is that it contains a dungeon where the first Prince of Wales starved to death. There was also a brief account of Jenner, referring to his grave in the chancel of the church. The learned stable boy having arrived, would not commit himself to any definite information but ventured the remark that "Vicar would know" and conducted us to the bottom of a lane whence we could see the Church of St. Mary's and the vicarage.

As nearly as I could understand, I was told that the Vicar was away birdnesting. This was finely in the tradition of Jenner's paper on the cuckoo, but considering the weather, seemed to be carrying a tradition somewhat too far. By wandering around I suddenly came face to face with the thatched cottage where Jenner took the lymph from the hand of Sarah Nelmes to inoculate James Phipps. I recognized it from the model reproduction in Burroughs, Wellcome's exhibit at the Chicago Century of Progress Exposition, and it is well I had been there because no plaque or plate or notice indicates why this fragile structure is preserved or what happened

there By Sherlockian cunning, we found the tomb It is marked simply "Edward Jenner" and his dates I liked that, but nowhere else in Berkeley is his name seen, there is not a statue or a tablet or a stone to one of the greatest Englishmen who ever lived

We returned for lunch, but alas for the enthusiasms of biographers when they describe their hero's meals The dining room at the Berkeley Arms was as cold as an enthusiastic New England audience The napkins were heavy with the damp chill of mortality The soup reminded us of the Irish famine victim's complaint about the relief kitchen, which Stokes liked to recite—"Soup, is it? Shure 'tis nothing but a quart of water biled down to a pint to make it sthronger" There was a piece of fish of the whiteness of virgin snow, which had been boiled until every vestige of animation had long since departed, and by its side with a thick white sauce, over the surface of which the congealing process of coagulation had done its deadly work That sauce tempted me and while the waiter was out of the room I inserted my clinical thermometer into its center I record as a solemn fact that the temperature was exactly 54 degrees Fahrenheit

Do not mistake me I admire the English And the thing I admire most about them is their ability to live in England And, furthermore, to me the greatest Englishmen who ever lived are those great and great-great-grandparents of mine who left England and settled in this land of furnaces and bathtubs, of sunshine and shad roe, of ice and mint, of cheap cigars and good coffee, and silk hats only on formal occasions

I had a Scotch hughball for dessert at the Berkeley Arms and then found there was no bus to Gloucester until morning But no enticement would induce me to try the sheets after sampling the napkins and I hired a car from the garage (Hired? We nearly bought it) and set off Then the heavens really opened The vale of Gloucester may be as beautiful as the Cotswald poets say, but for me it is a vale of tears In Gloucester Cathedral there is a figure of Jenner and a window dedicated jointly to him and his friend and biographer, John Baron

I thought on my journey home that someone should begin an agitation for a memorial in his own home for Jenner But then a restraining thought cooled me off Perhaps they don't want it One would have to approach the Vicar of St Mary's first Perhaps it would be better to turn the project over to an organized body—the College of Physicians and the British Medical Association

By contrast is a visit I paid in Italy to Arezzo and asked the hotel proprietor where Francesco Redi lived His face lit up He took me by the arm He said something to the cafe loungers and they accompanied us excitedly into the street The priest joined us I was conducted to the Via Redi and directed towards the villa Soon I stood before two lovely old gates and passed up through the rows of cultivated plants until I stood at the entrance of a fine manor house There a marble plate proclaimed

Qui Nacque E Abito
 Francesco Redi
 Insigne Letterato E Poeta
 Sommo Nella Medicina
 E Nelle Scienze Naturali

One could easily imagine as one stood looking over that peaceful farm how naturally the lord of the manor would turn to those studies in insects and spontaneous generation that made him sommo in medicina et scienze naturali

A soft voice behind me said something, and I turned to find a woman dressed, almost shabbily, in that severe black dress which Italian women affect. She had a shawl over her head and looked almost like one you used to see at Ellis Island. Yet what she said was that he was an ancestor of hers and she graciously conducted me to the chapel where all the Redis, save, apparently, Francesco himself, are buried.

I do not say that this treatment is typical of the English and Italian attitude towards their great dead, but it suggests a lesson to us.

What of the condition of our American medical shrines? I suppose there would be a very general agreement that the most important American contributions to medicine were, first, the introduction of general surgical anesthesia, second, the foundation of the physiology of gastric digestion, third, the establishment of successful ovariectomy, fourth, the suggestion of the contagiousness of puerperal fever, fifth, the discovery of replacement therapy for diabetes, and, sixth, the discovery of specific replacement therapy for primary anemia. Of equal importance as shrines of service are those institutions which have continuously, from their establishment, rendered such distinguished service to our people—our first hospitals, Pennsylvania and Bellevue, and the Surgeon-General's Library.

The South and the North share the honors of anesthesia. The Massachusetts General Hospital, as you know, keeps alive the memory of that dramatic morning of October 16, 1846. At Jefferson, Georgia, Long is represented by a granite shaft.

I have not been to Mackinac Island for many years and am indebted to Dr. Carl S. Cook of Mackinac Island and Dr. A. C. Tiffany of Mackinaw City, Michigan, for the following information:

"Alexis St. Martin was shot June 6, 1822 in the basement of what is now the Early residence at the foot of the hill leading up to this old fort. This building is still in excellent repair but gables have since been built out on the second floor. Dr. Beaumont first attended St. Martin in this basement, but immediately moved him up to the hospital at the fort. This hospital is a small one-story frame building within the fort walls. It was used as the Post Hospital until 1858 when the Surgeon's Hospital was built because of need for more room. Beaumont's hospital was then used as the

quartermaster's store until the final evacuation of the fort in 1895. From then it stood vacant until 1923 when it was rehabilitated and restored as an emergency hospital. An organization of Mackinac Island people and summer residents has equipped the old building with the necessary surgical appliances and it is now used for surgical emergencies. The present operating room is in the old part of the building, and the entire building has been refinished. The hospital is now kept up by gifts made by summer visitors. It is called Beaumont Emergency Hospital.

"There is no plaque marking Beaumont's home, but according to Meyer's book on the life of Beaumont he lived in the east quarters of the Stone Barracks, still standing.

"In 1900 a monument was erected to honor Dr. Beaumont. This was presented by the Upper Peninsula and the Michigan State Medical Societies. This monument is placed just within the Fort walls facing the Straits of Mackinac."

The inscription on the monument says, "Near this spot Dr. William Beaumont, U. S. A., made those experiments upon St. Martin which brought fame to himself and honor to American medicine. Erected by the Upper Peninsula and Michigan State Medical Societies June 10, 1900."

Our city of St. Louis here where we meet tonight, was, for many years, the home of Dr. Beaumont, but Missouri is neither the site of his birthplace nor the locale of those labors which made him famous. His birthplace in Lebanon, Connecticut, is the site of a stone shaft, dedicated on June 29, 1926.

The third spot of first rate importance as an American medical shrine is Danville, Kentucky, where Ephraim McDowell performed the first successful ovariectomy. In 1879, the Kentucky State Medical Society rescued the graves of Dr. McDowell and his wife from imminent dissolution and erected monuments over them. On this occasion Dr. Samuel D. Gross of Philadelphia delivered the oration and Dr. Lewis S. McMurtry, afterwards president of the American Medical Association, accepted the gift in the name of the Kentucky State Medical Society.

Dr. McDowell's property—his residence and office, where this classic operation was performed—was for many years badly neglected, although not because of lack of effort on the part of the Kentucky State Medical Society and other interested organizations.

Dr. Schachner, one of the biographers of McDowell, tells of visiting the house while it was a negro boarding house and as he was going upstairs the landlady pulled off a piece of lath from the disintegrating plaster wall and handed it to him as a souvenir.

Within recent years it has been possible for the McDowell Memorial Committee of the Kentucky State Medical Association to acquire this building, and when I was there last fall it was in process of repair and reconstruction. In the course of the research work necessary to secure the plans for

the restoration, the fact was uncovered that the adjoining property, which is also in good condition, was McDowell's Doctor Shop and Apothecary. The committee is trying to raise sufficient funds to purchase this property, which will cost \$3,000 00, so that the entire McDowell block may be restored. For this work one of our guests at this convocation, Dr. Irvin Abell, has been so largely responsible that it is a pleasure to record our indebtedness to him.

The locale of Holmes' work on puerperal fever is indefinite. And there is no special single institution where Whipple, Minot and Murphy's work on liver in Addisonian anemia was completed. But with this, as with Toronto's honorable shrine of insulin, we can afford to wait a long time before it will be appropriate to memorialize them.

These are our proudest memories, but there are others, hardly less epochal ones. It is appropriate to my subject tonight, since Dr. Bradley is our president, to recall that in that part of Kentucky near Danville, that beautiful fertile region of the blue grass of Kentucky, there is, in Dr. Bradley's own city of Lexington, the site of the first medical college west of the Alleghenies and the fifth in the United States, Transylvania College.

The medical faculty no longer functions in Lexington, but there is a reminder of this early center of medical education still intact. Early in the nineteenth century the trustees raised a considerable sum and sent Charles Caldwell, Professor of Medicine, to Paris to purchase a library. "The time of my arrival in Paris," he wrote, "was uncommonly propitious for my purpose. The wastelays of the French Revolution had not entirely passed away. The libraries of many wealthy persons had found their way to the shelves of the bookseller. I found and purchased at reduced prices no inconsiderable number of the choicest works of the fathers of medicine from Hippocrates to the revival of letters." These books are still in the general library building of the University—a beautiful and typical collection of an eighteenth century physician's books. They cry out for proper housing.

From this area of Western Kentucky as a center, there came the pioneer medical profession of this part of the world—of Cincinnati, St. Louis and Missouri. Since we are meeting on the very ground which was the hub of the settlement of this western territory, may I venture to recall to you some recollection of the life and experience of our pioneer Missouri physicians?

I have here in my hand a little book, one of the rarest examples of Americana, which is entitled SAPPINGTON ON FEVERS. It was printed at Arrow Rock, Missouri, in 1844.

Those of you (naturally I address particularly the Missouri part of our audience) who have visited Arrow Rock, which is about midway between St. Louis and Kansas City in a beautiful rolling countryside reminiscent of the blue grass region of Kentucky, will remember the old Arrow Rock

FIG 1 John Sappington From the portrait by George Caleb Bingham

Tavern which was close to the home of John Sappington, and which now exhibits a museum of his case books, saddle bags and other relics

John Sappington was born in Maryland in 1776. His father joined the tide of western emigration and moved to Tennessee, settling in Nashville. John Sappington studied with his father as preceptor and later was associated with him in practice in Nashville. In 1814 he rode to Philadelphia on horseback, where he attended for one year, from 1814 to 1815, a course of medical lectures and received a diploma from the University of Penn-

sylvania He heard the arguments for and against the violently depletive treatments that the followers of Rush and Cullen taught and practiced in the treatment of fevers Returning to Tennessee, he emigrated in 1817 to Missouri and located in what was then the western frontier settlement of Howard County Two years later he moved across the river and settled in Saline County, near Arrow Rock

The medical problems of this territory were quite as grave as any other danger to which the settlers were exposed There was a well defined sickly season, starting in July and extending into September until the first frost Fever and chills were nearly universal visitations and the farmers expected so much incapacitation at this time that they made particular efforts to have their crops and other important matters attended to before the onset of the sickly season

FIG 2 The Tavern at Arrow Rock, Missouri It houses many Sappington relics

The cause of these fevers and agues was unknown Daniel Drake writing in 1830, says "There is a noxious gas given out throughout the great Mississippi Valley system which affects the people of the west and south" This noxious gas theory is the one which gave malaria (mal air) its name Drake afterwards discarded this noxious gas theory

In Morse's "Western Gazeteer" in 1810, in regard to Louisville, Kentucky, it is said that "its unhealthiness due to stagnating waters back of the town has considerably retarded its growth"

Early settlements in Howard and Saline Counties, Missouri, were frequently abandoned due to the prevalence of shaking agues

It is to the credit of Dr John Sappington, and it is the merit which has given his book permanent value, that he early recognized the specific therapeutic nature of quinine in these autumnal Valley fevers. Let me emphasize that it was quinine on which he relied. Daniel Drake preferred, in many cases, Peruvian bark to quinine but Sappington wrote "The names of Pelletier and Caventou, who first separated the pure alkaline salt, called quinine, from the bulky and inert mass in which nature had placed it, deserve to be remembered with gratitude by all mankind."

In this particular community, contiguous to our meeting place tonight, Sappington's influence was very strong. It is not too much to say that his advocacy, in season and out, of the virtues of quinine did much to make this section a healthy place of residence.

FIG 3 Dr Sappington's grave in the family cemetery at Arrow Rock. In this same cemetery are buried two governors of Missouri, C F Jackson and M Marmaduke.

He had by no means an easy time of it. His few professional brethren had been strongly imbued with the virtues of the depleting system of Rush, under whom many of them had sat. He probably shared, as Dr Thomas B Hall suggests, Oliver Wendell Holmes' opinion of Rush's epigram, "Medicine is my wife and Science my mistress," of which Holmes said, "I do not think that the breach of the Seventh Commandment can be shown to have been of advantage to the legitimate owner of his affection."

Even so fair minded an inquirer as Dr Daniel Drake was unimpressed by Sappington's ideas. Drake was a great influence all over the Mississippi Valley in those early days.

His "Western Journal of the Medical and Physical Sciences" was a source of light and comfort to physicians all over the West. At a time when the companionship and advice of fellow physicians was keenly missed on account of the sparsely settled land, the pioneer physician found in this journal both accounts of medical progress in the great centers of the world and also accounts of the local diseases of his own territory—new, strange and largely unrecorded in textbooks.

These accounts came largely from the pen of Drake himself and were the basis for his really major contribution to medical science—his “Prin-

cipal Diseases of the Interior Valley of North America” (1850) To collect material for this, Drake traveled restlessly up and down all our river valleys He visited Arrow Rock, Missouri, some time about 1835–1840, probably because he had heard of the fame of Dr John Sappington and his treatment of autumnal fevers Sappington condemned the depleting treatment of purging, vomiting and bleeding, because all that is necessary to effect a cure is quinine, “one grain every two hours, day and night”

Drake records (p 170, Interior Valley) a visit to Arrow Rock and a conversation with Dr Price, who was Dr John Sappington’s son-in-law

DR. JOHN SAPPINGTON'S ANTI-FEVER PILLS.

DESCRIPTION AND TREATMENT OF INTERMITTENT, OR AGUE AND FEVER AND BILIOUS FEVER, AND ALSO DIRECTIONS FOR PREVENTING THEIR INCEPTION AND RETURN

1st.—OF INTERMITTENT, OR AGUE AND FEVER.

I consider all fevers of an intermittent character which cool off once in twenty-four hours, whether preceded by a chill or not, or whether the chill and fever rise and continue together, or if there be no chill at all. Sometimes fevers of this character continue twenty four or forty eight hours without an intermission, and sometimes it occurs every third day only. Nine tenths of the fevers of this State and most other States of this Union, partake more or less of this character, and in all their various appearances the treatment should be the same.

TREATMENT—If the patient prefers taking a purge or purge before he commences the use of this medicine, I have no objection, but it is rarely if ever necessary. A grown person will take for a dose a pill or common sized teaspoonful of the liquid* every two hours, both night and day, until the disease is broken, (always observing to shake the liquid before used,) and children will use less in proportion to age, for instance, a child eight or ten years old will take thirty or forty drops, one of three or four years old will take fifteen or twenty drops, and infants three or four weeks old will take from three to six drops, and repeat and continue as recommended for grown persons. Should the bowels be too costive, or in other words, not purge once in thirty-six or forty eight hours, give broken doses of salts, or oil, or injections, and should they purge often than twice in twenty four hours, give six or eight drops of laudanum two, three or four times a day until the looseness is restrained. Diet to be such as is suitable for a sick person, drink cold water.

2d.—BILIOUS FEVER.

This is a more obstinate and dangerous disease than Intermittent, or ague and fever, there are generally three or four days of indispotion previous to the development of fever, and generally chilly sensations for a day or two after.

When this disease is properly formed, it rarely yields to any treatment under eight or ten days, and sometimes a much longer time.

TREATMENT—In the first stage of the disease, I give a purge or one or two small doses of calomel or some other medicine that will operate upon the stomach and bowels, under any circumstances I object to giving more strong medicine, and am decidedly of opinion that a frequent repetition of them does more harm than good. After thus operating on the stomach and bowels and even without it, if the patient has become weak from the duration of disease, I commence with the pills or drops and give a dose every two or three hours, with Virginia snake root or some other sweating tea, such as hyssop, sage, or balm. Should the patient suffer much pain in the head, back, or elsewhere, give twenty or twenty-five drops of laudanum at night, children should take less, corresponding to their ages. Should the patient become debilitated from a continuation of the disease, and particularly if the hands and feet become cold, give a portion of toddy or wine every three or four hours, continuing all the time the use of the pills or drops until the disease is broken. I would prefer the bowels to be in rather a costive

than laxative condition, but should they become too inactive give oil, or broken doses of salts and injections, or if they become too loose, give six or eight drops of laudanum, two, three or four times a day, until the looseness is restrained. Diet should be light, and taken often, but in small portions at a time, drink cold water.

3d.—OF PREVENTING THE INCEPTION & RETURN OF AGUE AND BILIOUS FEVERS

The remedy I recommend for the cure of these diseases, will prevent their formation if taken in time. If used as a PREVENTIVE, a person should take three or four doses a day for seven or eight days in succession, then discontinue it for ten or twelve days, when it will be again used as above directed, and so on until the sickly season has passed by, persons residing in unhealthy situations, or travelling through sickly districts of country, will find the PREVENTIVE plan greatly to their advantage. To prevent relapses of ague and bilious fever, an individual would do well to take three or four doses of the medicine a day until his strength and complexion are restored particularly if he has had several relapses already.

The reader will find a considerable change made in these when compared with former directions, this has been produced from the fact that my WORK ON FEVERS is now in general circulation, and that almost every one can get a book who desires further information on these or other fevers on which it treats. Moreover, Physicians, Druggists, Apothecaries, and many other individuals, are now making and offering to the public, pills purporting to be of the same materials and quality of mine and which in many instances, no doubt, are greatly weakened as well as adulterated, and believing that in this manner frauds will be ingeniously practiced, I have caused a fac simile of my signature to be pasted around each box and these new directions will now accompany the genuine Sappington Anti Fever Pills, instead of being tied around them as heretofore.

These Pills I can recommend as being equal and similar in every respect to the pills formerly sent out by me and that persons can avoid imposition by buying THESE pills instead of other pills of DOUBTFUL strength and purity.

As the community as well as the profession are partial to acting on the stomach and bowels with some purgative medicine, and as I have admitted in my Treatise on Fevers that it is generally proper, and sometimes essentially necessary that some purgative medicine should be taken by the patient before he commences the use of my Anti Fever Pills, to remove any indigestible or bad accumulation from the stomach and bowels, Dr Wm Price, of Arrow Rock, Mo, my son in law, has prepared what he conceives to be a suitable purgative for that purpose, to accompany the Anti Fever Pills, and I am much inclined to the opinion that he can prepare as good a medicine of the kind as any other person—by my advice, however—to be taken as often only, and under such circumstances as is recommended in my Treatise on Fevers, or as is advised in the directions around my Anti Fever Pills.

*For grown persons or children, who prefer taking medicine in a liquid form, it can readily be prepared by any one in the following manner, viz pound twelve pills well, put the preparation into a vial, and add two common sized tablespoonfuls of water or whiskey to it, spirits are best, and it matters but little what kind of spirits are used. Any quantity of the liquid may be thus prepared by increasing or diminishing in a just proportion the quantity of ingredients above mentioned.

January, 1848

JOHN SAPPINGTON, Sahne Co, Mo

Price One Dollar per Box.

FIG 5 Advertisement of Sappington's pills

He probably met Sappington, but apparently they conceived no high opinion of each other. Drake learned nothing from Sappington's advocacy of the specificity of quinine. He recommends, under treatment of autumnal fever (p 782) catharsis with calomel and emesis with tartarized antimony, and bleeding. This prepared the patient "for the reception of the bark and other tonics." Quinine he regarded as a tonic only. His conception of the problem was far inferior to that of Sappington, the backwoods general practitioner, whose mind went straight through to the conception of the specific action of the drug.

A recorded experience from a physician's own lips of the classic form of treatment is that from Dr James C Finley who, in a medical periodical in 1830, told of his own experiences. By his own direction he was violently purged and had an emetic-cathartic administered. This treatment was continued for six days when "Dr Childers, a physician of great observation and experience, who very kindly attended him during the remainder of his illness considered him to be out of danger and prescribed the Sulphate of Quinine." He said his system was completely prostrated by the end of the third day. He became delirious, which was attributed to the action of the quinine and the drug was discontinued. After that he became comatose and all hope for his recovery was abandoned. When he did recover consciousness "the mind as well as the body long remained in a state of infantile weakness."

In the first chapter of his treatise, Dr Sappington gives "The author's reasons why he has departed from the practice of the old school physicians and all others in the treatment and cures of fevers." He states his disapproval of the teachings of Rush and Cullen "which was chiefly that of bleeding and acting on the stomach and bowels with emetics and cathartics as long as they thought the patient could stand them." He suggests that quinine is a tonic and not a stimulant and "is not injurious when taken in the hot stage of fevers as has been frequently said of it."

He carried this idea over into the treatment of yellow fever in which the depleting system must have been particularly exhausting, added to the natural depleting effect of the disease.

Slowly his ideas gained ground and he won converts among his professional colleagues. One physician, Dr W H Shelton, was led to throw aside the teachings of Rush and to use Sappington's pills as directed and marvelled that he was able to cure three hundred cases of fever without once resorting to the lancet.

A typical experience was that of Dr George Penn, a graduate of Jefferson Medical College, who came to Saline County in 1826, riding all the way on horseback. He formed a friendship, and afterwards a partnership, with Dr Sappington. Let me record one of his experiences as retold by Dr Thomas B Hall.

"John bringing a sack of corn with him to the mill reaches Jonesboro at 4 p m, on a crisp, clear December day. He leaves word for the doctor, who is out, to be sure to come that night to see his sister.

"Dr Penn, returning home from his rounds, already having ridden fifteen miles in his visits to the sick, receives the message and after eating his supper, prepares for the trip. All his practice is done by riding, the roads making any other means of transportation out of the question. In his stable are two horses and a mule. This latter animal being recently introduced to Missouri by the Santa Fe traders, from Spanish settlements around Santa Fe.

"This is how we acquired our famous Missouri mule, and although it is hard to believe, some were esteemed for their good riding qualities, in addition to their recognized endurance. The mule and a large white horse bear the doctor during his day travels, but by night he rides a small sure-footed sorrel, which his Negro servant now brings for him to mount. His servant properly fastens the saddle bags to the saddle. The Doctor with his pipe lighted by an ember from the hearth, places a large calibre, loaded, flint lock pistol in a holster, which he straps around his waist, mounts his horse and is off on his long trip. Crossing Salt Fork, he soon leaves the skirt of timber and is on the prairie, where the narrow trail leads through prairie grass which extends as high as his horse's head. Now and then he comes to an open place where the grass has been burnt off. Forging Blackwater, he rides from a timbered section to the prairie again and within one and one half hours from the time he has left his home, reaches the two-room log cabin of Finley, in a timbered strip near Heath Creek.

"Entering the large room of the cabin, which is lighted by a blazing fire in the large fireplace, he is greeted by Finley and his wife and the least bashful of their seven children. The room is scantily furnished, with home made furniture, in one corner is a spinning wheel, in another three long heavy flint-lock hunting rifles and a smooth bore flint-lock musket. In front of the fireplace, the two older boys are running bullets and cutting round patches from the buckskin for the rifles. The atmosphere is still full of the odors of the evening meal, cooked in the open fireplace.

"The father takes, from the mantle, a shallow open iron pan, which is filled with melted grease and has a neck out of which protrudes a wick made of tow. Lighting the wick from the hearth, he brings this crude light for the doctor to examine his daughter, aged five, who lies apathetically, covered with a buffalo robe, in a trundle bed in one corner of the room.

"An examination quickly confirms the doctor's preformed opinion of the case, for he had prescribed much quinine for the Finley family during the months of August and September and he remembered that Mrs. Finley had told him at the camp meeting on Salt Fork that it was a constant battle to force the bitter quinine down her little daughter and that she frequently became nauseated and vomited.

"A recurrence of the ague was to be expected and the child's large spleen settled the diagnosis. Drawing the hickory stool on which he is seated near the fireplace so as to have a better light and more warmth, he seats himself and places his saddle bags across his knees, one on either side, the

broad leather band connecting the bags, in this way making him a work bench across his knees. In one compartment of his bags are two, 3-ounce bottles, one containing quinine sulphate and the other calomel. He asks the father for a cupful of whiskey, which is quickly obtained from the two-gallon jug in one corner of the room. Fortunately the family has a four ounce bottle which has a cork. This is filled with the whiskey and held near the doctor, who has the bottle of quinine on the large leather band passing over his knees, thrusts a knife with a long narrow blade which he carries with him for this particular use, into the open quinine bottle. His practiced eye can tell to $\frac{1}{16}$ of a grain, the amount of quinine sulphate necessary to make two or four grains when balanced on the point of the knife. Measuring in four grain doses and counting carefully the knife eight times dumps its load in the four ounces of whiskey. This gives him a dosage of one grain to the dram and he has found it the best way to give quinine to infants and children. A few drops from a vial labeled 'Elixir of Vitrol' are added to the four ounce bottle to increase the solubility of the quinine.

"Two teaspoonfuls of this medicine are administered to the child with instructions to give thereafter, one teaspoonful every three hours night and day. When about to leave, Mr. Finley states that he has no money to pay him, but offers to pay his bill with two sacks of meal worth about 75c a sack. This the doctor assents to and instructs him to leave the meal at the mill at Jonesboro, where he already has a good many bushels to his credit for his professional services to other patients.

"Thus he expects to sell for good Spanish coin to the Santa Fe traders the next spring. Mounting his horse, he starts home by the same trail."

The amount of quinine Dr. Sappington used is an index of the thoroughness with which this countryside was de-plasmodiumed. John Farr of Philadelphia was the first chemist in America to manufacture quinine. He expressed great surprise at Dr. Sappington's orders of 500 pounds at a time. Indeed, Mr. Thomas Hart Benton tells me that it was a legend in his home that the reason Dr. Sappington first advocated quinine was that he ordered a hundred ounces and by mistake received a hundred pounds. He had a supply to be got rid of and he was a practical man. But then, as everyone knows who has seen Mr. Benton's murals, he has a somewhat mordant sense of humor.

Other diseases in this country unfamiliar to us, the successors of the pioneer physicians, were Asiatic Cholera and Typhus and "Black Leg," which was scurvy, so called on account of the petechial hemorrhages on the skin of the legs.

Dr. Sappington's drugs which he carried in his saddle bags were, besides quinine, opium in the form of powder, laudanum and paregoric, mercury, iron, oil of chenopodium, digitalis, arsenic in the form of Fowler's solution. He performed many vaccinations, carrying the lymph on bone points. He had no hypodermic syringe but allayed pain by injecting a small enema of sweet milk containing 30 to 60 drops of laudanum. He practiced counter-irritation by the free use of mustard plasters and Spanish fly ointment.

Dr Sappington's popular reputation today among those who have heard of him rather vaguely is that he was an irregular practitioner, an advertiser and almost a quack. This is partially, but not entirely, deserved. He was so passionately convinced of the truth of his cause—that the way to make the countryside healthy was to distribute quinine generally—that he felt any means justified the end. He sold his fever specific to the public. They were widely known as Sappington's Anti-Fever Pills. He excused this conduct on the grounds that there was a tremendous prejudice against quinine and if he had sold them as quinine they would not have been used, whereas he could introduce them as Anti-Fever Pills. He sold his book to the laity and wanted to get it into their hands because he realized that the profession did not accept his view perhaps they were too educated and it must be remembered that personal reminders of his existence to the extent of professional cards in the paper was the country practitioner's common practice.

It was his habit on his rounds to scatter blue grass seed over the fields by the side of the road and to try to make Missouri resemble in verdure, Kentucky.

The story of the desecration of his grave has been frequently garbled. The actual facts, however, need no retouching. He had a dread of being buried underground, and he had a lead coffin constructed, which he kept under his bed—usually filled with apples. He died in 1854 and was duly interred in the lead coffin above ground, as directed. When the Civil War came along, the Confederates ran short of ammunition and someone called attention to the magnificent supply of lead exposed at Arrow Rock. So they were ordered to take as much lead out of the doctor's coffin as they wanted and in doing so mutilated it considerably so that, as I understand, the skull was exposed for a time. William Harvey, it will be recalled, was also "lapt in lead."

This John Sappington is the sort of figure whose memory should be preserved by us. Everywhere in the United States there are materials for the record of a complete history of medical practice there. In only a few instances have they been utilized. I have been made very enthusiastic by the publication of such works as the histories of medicine in San Antonio, Texas and Sullivan County, Indiana, lately published. This is far more appropriate work for the American medical historian than delving into incunabula or Babylonian mysteries.

This is neither the time nor the place for any specific recommendations. But I hope you will not think it presumptuous of me to suggest that it is one of the legitimate functions of this College to encourage and to aid the preservation of the memories of the figures and the landmarks of our glorious past.

Note. It is a pleasure for me to acknowledge my indebtedness in the preparation of this paper to Dr Thomas B Hall of Kansas City. I have utilized not only the results of his scholarly researches into the history of Dr Sappington, but often his very words. See "John Sappington, M D" by Thomas B Hall, M D, Missouri Historical Review, January, 1930.

THE RELATION OF PULMONARY FUNCTION TO FIBROSIS AND EMPHYSEMA *

By JAMES ALEXANDER MILLER, M D , F A C P , and ISRAEL RAPPAPORT,
M D , *New York, N Y*

IN a recent publication ¹ we presented a preliminary communication suggesting our ideas of intrinsic lung function. At that time we reached the following conclusions:

(1) The intrinsic function of the lungs consists in their alveolo-capillary surface-creating and self-cleansing power.

(2) Disturbance in these functions manifests itself by obliteration of some and compensatory hyperfunction of other lung areas.

(3) In pulmonary fibrosis there is a permanent loss of functioning lung units, due to failure of the intrinsic self-cleansing function, and in emphysema there occurs an irreversible loss of retraction power in the compensating lung units where the operation of the intrinsic function of creation of new breathing surface fails and the available spaces are merely overstretched by the operation of extrinsic breathing.

It is our present purpose to further elaborate and elucidate the ideas previously suggested.

THE PREVAILING CONCEPT OF LUNG FUNCTION

The prevailing ideas concerning lung function and the nature of pulmonary fibrosis and emphysema may be briefly summarized as follows. The respiratory system of air passages and pulmonary alveoli serves the purpose of ventilation. In this function the myoelastic elements of the airpassage system play the rôle of an active force in the expiratory retraction of the lung. The main activity producing ventilation is, however, the activity of the neuromuscular apparatus of breathing in the chest wall and diaphragm. The lungs act as a mere air reservoir, and the chief purpose of the lungs is to afford the breathing surface necessary for gas exchange. The structures constituting the breathing surface play a merely passive rôle. According to these ideas pulmonary gas exchange is determined essentially by cardio-circulatory function which regulates the extent of blood circulation in the lungs. Circulation and ventilation are recognized to be closely correlated to meet changing conditions, as for example from rest to exercise. It is believed that to increase gas exchange in the lungs all that is needed is to increase the work of the heart to drive more blood through the lungs.

From the Tuberculosis Service, Bellevue Hospital, New York. Presented at the Clinical Session of the American College of Physicians, at St. Louis, April 22, 1937.

and to increase the work of the breathing apparatus, that is, the chest wall and diaphragm, so as to maintain adequate ventilation of the air reservoir in the lungs

According to this concept the lung, as compared with other internal organs of the body such as the kidneys, the liver, etc., has, strictly speaking, no definite function of its own. This concept was recently well expressed by Y. Henderson² as follows:

The lungs are peculiar organs in that they have little independent activity or self-regulation. Their activity is mainly determined and controlled by influences outside the lungs themselves. In their abnormal physiology the dominant influences are generally not developed in the lungs themselves, they are induced by conditions in other parts of the body.

It naturally follows that the prevailing ideas of the nature and pathogenesis of pulmonary fibrosis and emphysema are based upon the concepts of the lung and its limited function. Accordingly, pulmonary fibrosis is considered a purely structural process consisting of obliteration of the air-spaces by connective tissue the formation of which is elicited by inflammatory products or foreign matter deposits. This fibrous obliteration of the air-spaces interferes with the efficiency of the ventilatory bellows' action since it reduces the distensibility and retractility of the lung tissue. As the fibrotic process becomes more extensive, the resulting loss of reserve air-space becomes a functional handicap.

Emphysema also is looked upon as essentially a purely structural process consisting of a loss of elasticity and retractility of the tissues of the lungs of various etiology, much of which is still obscure. Here again it is held that these structural changes interfere with the efficiency of the ventilatory bellows' action and result in over expansion of the lungs because of the force of the breathing apparatus.

The prevailing, just outlined concepts about the nature and pathogenesis of pulmonary fibrosis and emphysema have been well expressed in the recent publications of McCann,³ Christie,⁴ Meakins and Christie,⁵ Kountz and Alexander.⁶

Clinical experience has, however, forced upon us the consciousness that there are many functional disturbances associated with these structural changes. Among others Knipping et al.,⁷ Richards and Cournand,⁸ have made extensive studies of these functional disturbances. However, these studies concerned themselves mainly with the disturbances of circulation and ventilation which affect gas exchange and which are considered as sequelae of the structural changes above noted. When these functions of circulation and ventilation fail, the eventual outcome is thought to be cardiac failure.

It is, therefore, obvious that in these prevailing concepts there is no suggestion that pulmonary fibrosis and emphysema might represent primary disturbances in the function of the lungs with a specific function of their

own, nor is there any suggestion that the functional failure which results from these conditions might represent organ failure of the lungs in the strict sense of that term

OUR CONCEPT OF LUNG FUNCTION

We postulate the existence of a special organ function in the lungs, analogous in every sense to the special functions of the other organs of the body. Studies of the situation existing in other organs show that the special function of each organ invariably consists in special adaptations of the structure of the units of that organ to some particular physicochemical process involved in its function. In every case the main purpose is to serve the exchange of certain substances between the blood and the specific cells of each organ. This may be either absorption into the blood of substances necessary for the life activities of these cells, or, on the other hand, the elimination of the waste products of cellular activity. The physicochemical processes involved consist chiefly of filtration of fluid and the diffusion and absorption of gases and solutes. The structure of each organ is adapted to perform its particular function.

Each organ consists of a vast number of individual units each one of which is endowed with far-reaching independence for function and also a great capacity for compensatory hyperfunction in case of failure of other units of the organ. The organ as a whole is active only in the case of an increased demand for function, and at rest only a fraction of the units are simultaneously at work. Barcroft⁹ recently described this situation for the case of the lungs as follows:

The lungs are not built for the animal as it stands or lies, they are built to subserve the needs of the animal when it is putting forth the utmost exertion of which it is capable.

Alternation of these fractions of the available organ units is the rule during rest. The structural adaptations characteristic of the organ units are linked up with the functional circulation and filtration processes, and together with the circulatory motor force behind these they form a functional mechanism which is adjusted to the pressure conditions prevailing in the circulation. This functional mechanism the motor force of which is the cardio-circulatory pump, is correlated with, and counterbalanced by, a parallel functional mechanism by virtue of which the structures of the organ units execute certain movements of adaptation under the effect of the pressures which prevail in their environment, or the effect of the tensions or active contractions inherent in their own tissues, which thus serves as another motor force behind their intrinsic functional mechanism. This is true of the kidneys, of the glands and many other organs, and we suggest that the same mechanism operates in the lungs.

STRUCTURAL AND FUNCTIONAL ORGANIZATION IN THE LUNGS

The characteristic structural units of the lungs are the air-spaces. As in the other organs we conceive that these units are endowed with far-reaching independence of action and great capacity for compensation one for another. These units function in alternation at rest, and this alternation is associated with shifts from the functional (pulmonary) to the nutritional (bronchial) circulation. The functional circulation is provided for by an exceptionally large capillary network, and there is an exceptionally abundant filtration of fluid from these capillaries into the air-spaces. We conceive that the intrinsic unit function in the lungs is served by a double motor mechanism the forces of which are acting in opposite directions, namely, the erectile force of the functional circulation which acts in a centripetal direction toward the lumen of the air-spaces, and, on the other hand, the air-space expanding force which acts in a centrifugal direction from the center of the air-spaces.

The specific physicochemical processes of gas exchange and evaporation require exposure of the circulating blood over the greatest possible surface which is constituted of a tissue membrane of extraordinary delicacy. We conceive, therefore, that it is the intrinsic function of the units of the lungs to adapt their structures so as to create such a surface, to maintain it constantly, and to regulate it under all circumstances in accordance with the requirements of the body for gas exchange and for evaporation in the lungs.

Thus, we have reached the conclusion that the creation, maintenance and regulation of internal surface adequate in quantity and quality for the momentary requirements of gas exchange and fluid elimination under all conditions is the intrinsic function of the lungs.

In our studies of this subject we have found that creation by function was implied already in Huntington's¹⁰ "selective theory" of phylogenesis of the lungs. The concept could not have been better expressed than by the statement "A man is really not winded but lunged," included in this brilliant essay. The outstanding studies of Heiss¹¹ on the embryology of the lungs have demonstrated that creation of an ever greater internal surface is the basic biologic principle of development of the lungs both before and after birth.

A Antenatal Development of the Lungs Embryologic development of the lungs takes place by biological growth of its primitive anlage consisting of an entodermal and a mesodermal component. Growth of the former results in an increase of the mass and size of the organ. As the remarkable studies of Marcus¹² have shown, growth of the mesodermal component increases the complexity of septal partitioning into new units of the organ. Wherever surface is to be greatly increased Nature resorts to such an infinite subdivisioning of available space. Antenatal lung development consisting of the centrifugal sprouting of the entodermal and the centripetal partitioning of the mesodermal component of the lung anlage, serves thus

the creation of a great number of organ units with a vast potential internal surface

B Establishment of Pulmonary Function at Birth By the recent outstanding work of Broman,¹³ Willson,¹⁴ Bremer¹⁵ our modern concepts of the functional development of the lung have become well established. This work has particularly served to confirm the concept that the first air-spaces of the lungs are produced by the mechanical disruption of the continuity of the entodermal lining of the lung units. Establishment at birth of two functional mechanisms acting in intrinsic lung function brings about the opening of the lungs' air-spaces and the creation of the breathing surface. The motor forces behind these two mechanisms are (a) centrifugal thoracic traction, as maintained by the permanent tonic activity of the neuromuscular apparatus of breathing (chest wall, diaphragm and bronchi), and (b) the centripetal erection of the pulmonary capillaries, as maintained by the pumping action of the heart. At birth these two mechanisms act together to disrupt the continuity of the entodermal covering of the lung units, to expand these into air-spaces and to expose the vast capillary surface of the lungs within the lumina of the air-spaces, which thus become separated from the outside air only by an extremely delicate membrane of the mesenchyme which is the carrier of the vascular system everywhere in the body. Disruption of the entodermal continuity is prepared for by prenatal degeneration and loosening of the lining of the terminal buds. Capillary erection is accomplished by marked increase in the pulmonary circulation as the ductus Botalli is kinked off and all blood begins to pass through the lungs. In the air-spaces thus created at birth there is established a permanent air depot (residual air) of the lungs since only a part of the air-spaces which are formed are allowed to retract at one time as function continues in alternating groups of units.

At the same time and in the same manner there is established in the lungs a permanent blood depot, that is, the large amount of blood which is rushed into the organ is transmitted to the systemic circuit only in fractions governed by the subsequent periodic rhythms of the heart and in proportion to the venous return.

It is our conception that once thus set in motion the just described functional mechanisms continue their uninterrupted course throughout life, with intrinsic lung function continuing to consist of air-space expansion and breathing surface creation by disruption of the entodermal continuity of the air-spaces and the pushing forward of the capillaries into their lumina.

C Postnatal Development by Combined Growth and Function Evidence of continued biological growth of the lungs after birth was brought forth, in addition to that already mentioned,^{13, 14, 15} by the work of Bender,¹⁶ Hilber,¹⁷ Tiemann¹⁸. With the more recent work of Bremer¹⁹ continued development of the lung throughout at least the upgrade period of life stands now conclusively proved. During the first years of life there is great

demand for additional breathing surface and air-space, which is met at first by the growth of additional new lung units. As the child grows and the intrinsic function of the lungs increases in efficiency and power, demands for increased function are being met more and more by increased function of the already available units. For a number of years, varying in each individual, there continues after birth the development of the lungs by increase of both growth and function. The principle underlying both these factors, growth and function, is internal surface enlargement by means of increased partitioning.

D Permanent Lung Function Structural Adaptation for Intrinsic Unit Function (a) *Adaptations of the membrane which serves as the breathing surface* Haldane and his associates recognized the fact that there must be some innate lung function other than that of a simple ventilatory process. They suggested that this consisted in gas secretion by the capillary endothelial membrane which separates the blood from the air-spaces. Haldane and Priestley²⁰ say

The tissue elements in which oxygen secretion occurs might either be the alveolar epithelium, the capillary endothelium, or both. It seems, on the whole, more probable that the secretory activity is localized in the endothelial cells of the capillaries since they are in direct contact with the blood.

No evidence of such secretion has ever been forthcoming. But there has been a considerable amount of new knowledge recently accumulated in the pioneer work of Landis²¹ and that of Peters²² concerning the nature of the activity of the capillary endothelial membrane in the tissues of the body in general and in the special organs in particular. We now know that it is the function of this membrane to regulate its permeability in accordance with the type of capillary filtration required for the nutrition or function of the tissue or organ in question. This is now designated as the "blood-tissue barrier" function in which the endothelial membrane of the capillaries operates in association with the mesenchyme matrix which intervenes between every cell of the body and its particular capillary. The paramount physiologic rôle played by the uninterrupted stream of tissue fluid, which maintains the mesenchyme matrix in a semifluid state, has been particularly emphasized by Schade²³ and Beneke²⁴. There is evidence that capillary permeability implies transitory changes in the consistency of the endothelial membrane.

A recent publication of Field and Drinker²⁵ contains the following statement bearing upon the semifluid consistency of the mesenchyme matrix:

It seems apparent that these passages of particles through intact capillary membranes resemble the passage of a globule of mercury through a gelatin film, a migration which leaves no trace of damage. One sees the same sort of things on passing a needle through a bit of gelatin. Again no trace remains and at all times the gelatin has retained its integrity as a membrane.

In what is perhaps the most brilliant histophysiological study yet made on the living capillary wall Clark and Clark²⁶ very recently drew the following final conclusions:

The present observations have shown that the consistency of the blood vascular endothelium is characterized by extreme lability. The rapidity with which changes in endothelial consistency may take place, and the relatively minute stimuli necessary to elicit certain of these changes, together with their reversibility, are of unquestionable physiological importance and should be taken into account in any comprehensive consideration of the morphology and physiology of blood vascular endothelium.

As the consistency of the endothelial membrane softens, fluid escapes from the capillaries. The mesenchyme matrix which transmits this fluid is also of semifluid consistency in most tissues of the body but much more so

FIG 1 Prenatal unit

in some than in others. If we consider the extraordinary and constant mobility of the lungs, and the vast fluid filtration which, as shown by the studies of Terry,²⁷ Swindle,²⁸ constantly pours out from the capillaries of the air-spaces, it seems logical to assume that the consistency of the mesenchyme matrix in the lungs must be capable of unusual changes. In the lungs, gas exchange is the reverse of that in all other tissues of the body, as here oxygen diffuses into and carbon dioxide diffuses out of the blood. With this reversed gas exchange process there is closely linked a physico-

chemical process which must play a rôle in the unusual and characteristic consistency changes which make possible the histostructural changes which underlie intrinsic unit function. In our conception of intrinsic lung function we postulate definite consistency changes in the mesenchyme matrix as well as in the endothelial membrane of the lungs' capillaries as a part of the

FIG 2 Unfolding and partitioning with establishment of respiration

structural adaptation of the organ to its particular function. We suggest that these changes in consistency in the endothelial membrane and in the semifluid mesenchyme matrix of the lungs are correlated with the functional mechanisms which act in intrinsic function. Thus, centrifugal thoracic traction acting upon the softened structures of the units operates as the air-space expanding force, while the centripetal erectile force in the capillaries is allowed to press forward within the softened and thinned-out mesenchyme layer. The springing-forward into the lumen of the air-spaces of these capillaries constitutes breathing surface creation.

The drawings here attached represent an attempt at schematic illustration of our concept of breathing surface creation in intrinsic unit func-

tion We are showing the lung unit in the prenatal state (figure 1), its subsequent unfolding and partitioning with establishment of respiration at birth (figure 2), and finally the alternation of resting and functioning units as indicated by the great differences in breathing surface made available by simultaneous opening as well as subdivisioning of the unit by the great number of mesenchymal partitions carrying the capillaries into the lumina of the air-spaces (figure 3)

FIG 3 Alternating resting and functioning units

(b) *Adaptation of the other structures of the units* In animals with low gas exchange requirements (amphibia) the air-spaces of the lungs are completely lined with epithelium and the lungs are perfused only periodically, the circulation in the organ as a whole being short-circuited from the right ventricle to the aorta, just as it is in the human fetus. In animals with higher gas exchange requirements (birds) the lungs consist of one large air-sac with a separate air inlet for fresh air and an outlet for used air, one capillary network being placed in the center of the air-sac, there is no tissue layer between the capillary surface and the air in the sac, the breathing surface being altogether naked.

Man stands between these two extremes as far as gas exchange requirements are concerned. Accordingly, the internal surface of the human lung is naked only in part, and while the organ as a whole cannot be shunted from the circulation, partial shunting is possible within the individual units. This we construe to be a structural adaptation for increased unit function. For years anatomists have debated the question as to whether the air-spaces of the human lung are lined or naked. The answer from our hypothesis would be that it is lined at some times and naked at others, depending upon the alternating periods of rest and active function. Resting units are fully lined, their walls are thickened and they have the retracted appearance of what Seemann²⁹ has designated as "physiological atelectasis." The recent and particularly exact studies of Verzar³⁰ have given us conclusive proof of the truly physiologic nature and prevalence of such atelectatic areas in the lungs normally. The functioning units are expanded, their walls thinned out, their epithelial lining discontinuous, with the cells few and far between, leaving naked stretches where the capillary surface is exposed, with only an extremely thin mesenchyme membrane separating it from the air-spaces, as was so well demonstrated recently again by Clara.³¹

In the resting units the circulation is for nutrition the blood supply of which Daly³² has recently again shown to be coming from the bronchial arteries by anastomoses with the capillary net of the air-spaces derived from the pulmonary artery. That these capillaries are thus perfused alternately by the nutritional circulation from the bronchial artery and a functional circulation from the pulmonary artery has been claimed already by Havlicek.³³ Perfusion for nutrition demands the intervention of a mesenchyme matrix different in quantity and in quality from that required for functional circulation. The original mesenchymal conditions prevail in the resting units which are being perfused only for nutrition, while in the functioning units the mesenchymal layer is softened and thinned out into a membrane of extreme delicacy adapted to functional circulation and filtration, and this constitutes the breathing surface in the functioning lung units.

The tidal volumes of blood are distributed between the functioning units by means of the functional capillary bed. Some blood is always held in the resting units as a blood depot which varies in proportion to the number of resting units. The existence in the lungs of such a blood depot was first assumed by Rappaport³⁴ and has been fairly substantiated by the recent work of Hochrein,³⁵ Pfeiffer,³⁶ Sjostrand.³⁷ Some blood passes the lungs by way of these depot channels which thus serve as shunting channels of the pulmonary circulation. Being shunted from the breathing surface of the lung units, the perfusion in these channels is greater as the requirements for gas exchange are less, as for example in sleep, and, on the other hand, is markedly diminished when the gas exchange requirements are increased, as in exercise, and a large proportion of the lung units are in active function. This accounts for the high oxygen tension difference between the alveolar

air and arterial blood at rest, and its disappearance during exercise, as found by Bock et al.³⁸

We conceive of increased capillarization to be the key to increased unit function in the lungs, just as it is in some other organs such as the kidney. Increased capillarization and increased capillary filtration result in the consistency changes in the endothelial membrane and the mesenchyme matrix above described, resulting in greater efficiency in the functional mechanism, and are a part of increased intrinsic lung function.

(c) *Self-Cleansing* Intrinsic unit function requires the most intimate exposure of as extensive and delicate a breathing surface as the momentary gas exchange requirements demand. This intimate exposure is present only for short periods and in a fraction of the units. But, when it occurs, the air-spaces are flooded by an abundant fluid stream which drains out into the lymphatics and air-passages, not only the fluid but also dissolved material and desquamated cells in the lumina of the air-spaces, laden with digested foreign matter. The self-cleansing rôle of the fluid stream was already appreciated by Irwin.³⁹ Intrinsic unit function automatically affords a self-cleansing of the air-spaces and of the breathing surface, so that we consider self-cleansing as a component of intrinsic unit function. The efficiency of self-cleansing depends upon the efficiency of the intrinsic function as a whole and fails when that function is disturbed.

E Lung Function (Intrinsic Unit Function) and Ventilation (Extrinsic Breathing) These are two altogether separate functions which are intimately correlated. The neuromuscular apparatus of breathing acts in both, but the distinction between intrinsic function and extrinsic breathing is very definite inasmuch as the former depends upon the permanent tonus, while the latter is accomplished by the periodic contractions and relaxations of the neuromuscular apparatus. This concept rests on the outstanding work of Hess⁴⁰ which established the fact that the neuromuscular apparatus of breathing (in the diaphragm, chest wall and bronchi) functions by maintenance of neuromuscular tonus, that the permanent state of inflation of the lungs is maintained by the permanent tonic component, and that the superimposed pulmonary excursions are accomplished by the shifts in neuromuscular tonus manifesting themselves in the periodic increased contractions and partial relaxations of the neuromuscular apparatus. Demonstration of the exact rôle of the "self-controlling," i.e., "proprioceptive" reflexes in the regulation of both the permanent tone as well as the periodic contraction of the neuromuscular apparatus of breathing was the contribution of Fleisch.⁴¹

Like capillary perfusion, intrinsic unit function is uninterrupted but operates in alternating groups of units. It depends on the constant negative pressure, that is, the permanent thoracic traction, which is maintained by the basic tonus of the neuromuscular apparatus of breathing.

Like cardio-circulatory function, ventilation, that is, the movements of

the lungs, is periodic, depending upon the rhythmic contractions and relaxations of the neuromuscular apparatus of breathing

Intrinsic unit function, however, is regulated in accordance with the momentary requirements of the tissues of the body and, like similar functions in other organs, is controlled by regulation simultaneously through chemical hormonal and vegetative nervous stimuli. The neuromuscular apparatus of breathing which acts both in intrinsic lung function and in ventilation is under the combined control of the vegetative and the voluntary (cerebrospinal) nervous system. For the transmission of stimuli from the vegetative to the voluntary sphere, which is necessary for this combined control, Nature has provided the proprioceptive reflex regulation, so called by Hoffmann⁴² who discovered these reflexes and revealed their significance. The permanent tonic activity of the neuromuscular apparatus of breathing which is active in intrinsic lung function is brought under vegetative nervous control by these proprioceptive reflexes. The manner in which the vegetative (regulatory) nervous system controls the tone and automatic contractions of the breathing musculature by way of the proprioceptive fibers traveling in the pulmonary vagus, has recently been discussed by Nakanishi⁴³ in a particularly illuminating fashion. The periodic ventilatory activity of the apparatus of extrinsic breathing, while chiefly under voluntary control, is also subservient to intrinsic lung function which is under vegetative nervous control.

Ventilation is thus always adapted to the momentary level of intrinsic lung function. With the demand for increased lung function, as in exercise, there takes place an increase in the intrinsic unit function and also in the number of functioning units, and with this ventilation must also increase proportionately. We conceive that there is considerable variation between individuals in their capacity for the adaptation of intrinsic function. Some individuals can meet the requirements for gas exchange by fewer units functioning with greater efficiency, while in other individuals the same demand must be met by calling upon the simultaneous function of a greater number of units. In the latter case quantity has to make up for quality, the air turnover must be proportionately greater and, consequently, the ventilation must be relatively increased. Thus it is seen that ventilation may compensate for intrinsic lung function to a considerable extent.

On the other hand, within the limitations of his capacity an individual may compensate for deficient ventilation by increased intrinsic function. We conceive that the true capacity for pulmonary function as a whole is the efficiency of the intrinsic lung function factor. Excessive ventilation is more often a sign of low pulmonary capacity, while low ventilation is more apt to be associated with an intrinsic lung function which is compensatorily increased rather than deficient. Direct support for this contention may be found among others in the work of Herbst,⁴⁴ but particularly in the more recent study of Thomas⁴⁵ in which he concluded that

It is important to realize that increase in residual air may constitute one factor in a method of increasing oxygenation of the blood and should not be accepted per se as evidence of reduced pulmonary efficiency

F Respiro-Circulatory Correlation That there is a definite correlation between the circulatory and respiratory functions is well recognized, although not by any means completely understood. For our purposes we wish to sharply distinguish the correlation which exists in general between ventilation and circulation, and that correlation which we assume to exist between intrinsic lung function and the pulmonary circulation proper. The ventilatory excursions of the chest promote the venous return to the right heart in one phase, and the action of the left heart in the other. This represents the correlation between ventilation and cardiocirculatory function in general. In our conception of intrinsic lung function the degree of functional capillarization in the lung is of fundamental importance, as are certain phenomena in the pulmonary circulation such as the blood depot function and shunting as above explained. Just as extrinsic breathing and intrinsic lung function are correlated with each other, so we conceive that the cardio-circulatory function of the body as a whole is coordinated with ventilation so as to adapt the changes in the pulmonary circulation to the demand of increased lung function.

FIBROSIS AND EMPHYSEMA AS INTRINSIC LUNG FAILURE

It is obvious that these concepts of intrinsic lung function must materially affect our ideas concerning the pathogenesis of fibrosis and emphysema. We have already indicated that one of the essential features of intrinsic lung function is the self-cleansing mechanism by which the air-spaces are kept clear and the breathing surface clean, by the constant and rapid elimination from the tissues of the lungs of everything which interferes with the forces operating in air-space expansion and breathing surface creation. This includes the elimination of large quantities of fluid, the disposal of many waste products reaching the lungs from the blood, and the disposition of extraneous matter reaching the lungs by inhalation and also through the desquamation of cellular material. We suggest that interference with the normal fluctuations in the consistency of the capillary endothelial membrane and also of the mesenchyme matrix, tends to bring about an increase in density and a hardening of the consistency of the mesenchyme. This materially affects its characteristic permeability and its mobility and thus interferes with its adaptations required in the operation of intrinsic unit function. This hardening and decrease of mobility also interferes with the self-cleansing function and thus leads to fibrosis with obliteration of the units affected. These changes may result from the inhalation of foreign matter, as in silicosis, or they may be the effect of inflammatory processes of various kinds, or they may be due to irritating toxic substances coming in from the blood, or they may be due to abnormal circulatory changes associated with disease.

of the heart or the kidney Fibrosis and obliteration of the affected units are the result

For whatever reason various lung units may thus be excluded from intrinsic function they still remain subject to the ceaseless air-space expanding force of thoracic traction Wherever capillary filtration and the associated alternations in the consistency of the mesenchyme matrix have ceased, the degree to which any individual lung unit may resist or must yield to expansion will depend upon the intensity of the thoracic traction force on the one hand, and upon the extent and rate of the increase and hardening of the mesenchyme on the other

Increase and hardening of the mesenchyme matrix obliterating the air-spaces constitutes fibrosis

Expansion of the unit without simultaneous breathing surface creation constitutes emphysema

These two processes go hand in hand and are, therefore, practically always to be found in combination Sometimes fibrosis will prevail over emphysema, while at other times the emphysema prevails over the fibrosis It thus lies in the very nature of intrinsic lung function coordinated with the mechanical forces in operation, that a unit permanently excluded from function must either become transformed into a fibrotic band or nodule which may either yield or resist to breathing, or it must be expanded into an ever greater air-space the elements of which are being gradually stretched out of existence When both of these processes occur in a conspicuously large number of units we speak of pulmonary fibrosis and emphysema which thus represent a manifestation of chronic failure of intrinsic lung function

Clinically the term emphysema is applied to permanent distention of the lungs to a degree which normally prevails transitorily in the increased function which occurs during exercise^{4, 5} Associated with this is a permanent increase in the residual air content of the lungs, which in turn implies a proportionate restriction of their vital capacity As in exercise so in emphysema expansion of the lungs beyond the rest volume takes place in response to a demand for increased intrinsic lung function, which is responded to by the simultaneous function of a greater number of units rather than a greater efficiency of the intrinsic function of the individual units Just as in exercise so in emphysema there is an individual limit to the possible expansion of the organ and to the feasible number of simultaneously functioning units compatible with the requisite degree of ventilation Ventilation must always increase proportionately with the increase of simultaneously functioning units The permanent state of expansion and the periodic excursions of the lungs both represent the activity of the neuromuscular apparatus of breathing The state of expansion depends upon the state of the basic tonus, and the periodic excursions upon the rhythmic contractions of this apparatus^{40 41} This is a reciprocal arrangement so that one can increase

only at the cost of the other if the basic tonus must increase to hold the lungs in greater permanent expansion, then the periodic contractions must diminish in amplitude, that is, ventilation must suffer in efficiency. Hence, if the number of functioning units must be increased beyond a certain limit this can take place only at the cost of ventilation.

Increase in the number of simultaneously functioning units represents a type of compensatory increase in intrinsic lung function, which results in better utilization of the lung air, i.e., relatively increased oxygen absorption. This has its limitations beyond which improvement in intrinsic function must be bought at the cost of decreased ventilation, i.e., carbon dioxide retention. This type of compensatory increase in intrinsic lung function takes place also when the interference is primarily with ventilation for some reason, as in obstruction to movements of the chest such as chest deformities, conditions immobilizing the diaphragm, or those interfering with bronchial function as in asthma and bronchial obstruction, etc.

With progressive obliteration of an increasing number of lung units more of the available units are called upon for replacement, so that the number of simultaneously functioning units increases as a matter of compensatorily increased lung function. This necessarily implies a corresponding increase in the permanent expansion of the lungs, and when this goes beyond the limit compatible with the requisite degree of ventilation we have emphysema associated with restriction of vital capacity.

This emphysema, however, is still compensatory in nature, although it may persist throughout life. But, in the final analysis it is only functional not structural in nature, and should the patient die during this phase little evidence of this emphysema will be manifest in the structures of the organ. This explains the great discrepancy between the clinical and the pathologic findings of emphysema.

When fibrous obliteration of the units reaches such proportions that the requisite number of units for compensatory function are no longer available, the force of thoracic traction acts to keep the still available units in constant expansion and tends to gradually overexpand them, so that the air-spaces become dilated and thinned out and may reach the stage of bullae so characteristic of advanced emphysema. These bullae represent air-spaces formed by the coalescence of lung units in which intrinsic function, particularly breathing surface creation action, has ceased. Emphysema thus represents air-space production without corresponding breathing surface creation.

We may conclude, then, that just as pulmonary fibrosis may in the final analysis be interpreted as failure of self-cleansing, so emphysema in the final analysis may be explained as failure of breathing surface creation.

Fibrosis and emphysema thus represent a form of organic asthenia of the structures which function in breathing surface creation and in self-cleansing. This asthenia manifests itself by the insufficiency of the erectile

force of the capillary blood flow and the drying-up of the stream of tissue fluid which normally pours into the air-spaces. Accompanying this there are functional changes in the quantity and quality of the mesenchyme matrix which plays the paramount rôle in both breathing surface creation and in self-cleansing. The result is an ever decreasing partitioning of the air-spaces, that is, loss of internal breathing surface, and increasing coalescence of the air-spaces, with no evidence of where the tissue elements have disappeared. The structures in which the reservoir of the function-bearing mesenchyme has become exhausted disappear in the self-cleansing process which acts ceaselessly in coordination with the uninterrupted air-space expanding force. Whole units and groups of units are thus cleansed out and ever larger bullae are thus produced.

This organic asthenia may represent a congenital weakness of the organ, or the result of damages and injuries produced by a great variety of pathological processes occurring during the life of the individual, and, finally, it may be the result of the natural involution process of old age.

All of these factors are naturally subject to many variations in the same individual and particularly between different individuals. Thus, the great differences in individual predisposition to fibrosis and emphysema in the younger age group are explained, as well as the variations in the period at which they develop among the more aged.

PULMONARY FAILURE AND DECOMPENSATION

We have thus indicated that according to our conceptions pulmonary fibrosis and emphysema represent a chronic decompensation of the function of the lungs. Clinically this is regularly manifested by the decompensation syndrome the most outstanding symptom of which is dyspnea.

As fibrosis and emphysema become more advanced we observe clinically episodes of more acute pulmonary decompensation. These take the form of more acute dyspnea, cyanosis, with evidence of pulmonary edema. These attacks may vary in intensity and duration and will often clear up temporarily. Finally, however, all cases arrive at the stage of acute pulmonary edema which has usually been interpreted to mean cardiac failure. According to our observations, however, it is not the heart which fails but rather it is its continuing compensatory effort which intensifies the pulmonary embarrassment. For, the more lung units are out of function the more the circulation must increase in the remaining available units. But, with such a vast proportion of the lungs' units failing to perform their function, the blood continuing to come into the lungs only increases the burden upon the decreasing number of still functioning units, and so these too become unable to arterialize and transmit the blood. We then observe complete failure of the lungs, manifesting itself in pulmonary edema. The self-cleansing function and the breathing surface creation having already been taxed to their full limit, also fail entirely, and the patient dies of acute pulmonary decompensation or failure.

Classification of xanthomatous diseases

Summary

INTRODUCTION

THE group of lipid diseases comprising xanthomatosis, Gaucher's disease and Niemann-Pick's disease has been considered in the newer literature, following the idea of L. Pick,^{85, 86, 87} as a disturbance of the lipid metabolism of the whole organism. In essential xanthomatosis, cholesterol and cholesterol esters, in Gaucher's disease cerebroside, and in Niemann-Pick's disease sphingomyelins are involved.

This paper deals with essential xanthomatosis only, on the basis of observation of different clinical groups of this disease. We have set as our task the elucidation of the pathogenesis of this disease and to investigate whether the basic disturbance is in the intermediary cholesterol metabolism or whether it lies in the xanthoma cell (foam cell) itself, the characteristic feature of the xanthomata.

To approach this problem it is necessary to discuss in detail our present knowledge of the normal metabolism of cholesterol, and to consider whether the facts warrant the general assumption that xanthomatosis is due to a disturbance of the cholesterol metabolism in the whole organism.

THE METABOLISM AND FUNCTION OF CHOLESTEROL

Whether the body is able to synthesize and to disintegrate the sterol-skeleton is a fundamental question. The possibility of a synthesis of the sterols has been investigated from different points of view. Gamble and Blackfan,⁴² carrying out balance experiments with infants on a milk diet, believed that cholesterol was formed in the body as shown by a greater output than intake. My coworkers and I¹²⁸ showed similar results in balance experiments on adults (if the present knowledge based on the work of Schonheimer,¹¹⁶ that plant-sterols are not absorbed, is applied to the figures of our experiments). At the same time Schaber and I¹²⁹ were able to substantiate the fact that the total amount of sterols increases in eggs during incubation. Today the synthesis of sterols in the organism is demonstrated beyond doubt in many experiments. I may mention the experiments of Schonheimer¹¹⁰ on laying hens, and also the studies of Jenke and myself¹³³ on dogs with bile-fistulas, which establish the fact that 2 gm. of bile acids are produced daily from dogs independent of the sterol content of the food.

It is not definitely known in which organs and cells the sterol-synthesis is accomplished. Cholesterol-determinations in cases of yellow atrophy of the liver¹³¹ and experiments on hepatectomized dogs,¹³² however, point to the liver. In both of these conditions we found a decided drop of total cholesterol in the serum.

The mechanism of the formation of the sterol-skeleton in the body,

however, is entirely unknown. It is not even possible to determine whether cholesterol and bile-acids are formed from proteins, carbohydrates or fats in the animal organism. Studies relating to this question by my coworkers Jenke^{130, 134, 56} and Schindel^{105, 106} on dogs with bile-fistulas produced no clear results. Only experiments on lower plants hint at the material from which the sterols in plants may be synthesized. According to Massengale, Bills and Prickert,⁷³ the amount of ergosterol formed by *Saccharomyces cerevisiae* depends on the amount of sugar present, and sugar is the only organic foodstuff in the basal medium supplied in these experiments. Polysaccharides occasioned the formation of greater amounts of ergosterol than did the monosaccharides. It is noteworthy that the presence of sulphite decreases the sterol production of yeast in such a solution (McLean and Hoffert⁶⁹).

The destruction of the ring system of cholesterol in the metabolism has not yet been proved. Patients suffering from nodular xanthomatosis with a very large amount of cholesterol in the blood exhibit a considerable loss of cholesterol when kept for a long period on a cholesterol-free diet. In two balance experiments about 20 gm of cholesterol disappeared within seven weeks without being recovered in the stools. The output of sterols in the period mentioned was low (Schonheimer,¹¹⁵ Schilling¹⁰⁴). Analyzing the whole bodies and excreta of rabbits, cats and mice after feeding cholesterol-rich diets, Menschnik and Page,⁷⁴ Schonheimer and Breusch¹¹² recovered only a part of the amount of cholesterol given. These experiments, however, indicate merely that cholesterol, fed and retained, cannot be found again with digitonin precipitation. A recent paper by Bertha Ottenstein⁸² clears up this supposed disappearance of cholesterol in the body, by showing a disintegration of the sterol-skeleton due to the action of bacteria in the intestine. She demonstrates further that colon bacilli from the large intestines are particularly active in this respect. Thus a deficit of cholesterol in balance-experiments may be due to bacterial destruction and not to disintegration of the sterol-ring system in intermediary metabolism. A gap in the sterol-skeleton produced only by irradiation of ergosterol with the formation of vitamin D is no proof of metabolic disintegration. As long as derivatives of sterols, indicating a decomposition of the sterol-skeleton, are not discovered, the destruction of the sterols in the intermediary metabolism is not conclusive. Summing up, it may be said that the synthesis of the sterol-skeleton in animals is evident but the destruction of the sterol-molecule in the metabolism is not proved.

The changes which the body is enabled to make in cholesterol are significant but few. By means of an esterase the alcoholic hydroxyl is esterified with different fatty acids. The esterification of cholesterol produces a change in its physical properties important for its absorption and transportation in the organ fluids as well as for the composition of the cell-lipoids. Although an esterase is present throughout the body, the liver plays an

important rôle in determining the ratio of cholesterol to cholesterol esters Schaber and I¹³¹ showed that the esters are diminished in the serum in cases of parenchymatous liver disease, a fact confirmed by many investigators

Schonheimer¹¹¹ substantiated the presence of dihydrocholesterol in the serum and in tissues in normal humans, later on demonstrating an increase of dihydrocholesterol in a patient with nodular xanthomatosis¹¹⁵ These experiments (Schonheimer and Hrdina¹¹⁶) gave evidence that dihydrocholesterol in the tissue indicates a reduction-process in the body Genuine reduction-processes are not known in the intermediary metabolism There are combined processes of hydrogenation and dehydrogenation coupled with an oxygen-acceptor It may be that the dihydrocholesterol in the tissue originates from such a process In contrast to dihydrocholesterol the isomeric coprosterol does not occur in the tissue or in the intermediary metabolism Allocholesterol, which is supposed to be the unsaturated stereo-isomeric sterol of coprosterol, is not discovered in the body according to Schonheimer¹¹⁴ Thus coprosterol must originate from cholesterol in the intestines In the formation of coprosterol from cholesterol a change in the steric configuration must be accomplished on carbon-atom 5 This steric transformation is supposed to be produced by activity of bacteria In a recent paper Schonheimer,¹¹⁷ by means of an ingenious method of adding deuterium instead of hydrogen to the double bond, indicated the probability of a mechanism of the steric transformation of cholesterol to coprosterol First, the stero-isomeric cholestenone is formed from cholesterol by oxidation and then undergoes reduction to coprostenone and coprosterol The possibility of a steric transformation of cholesterol in the body is of importance because the bile acids are members of the coprosterol-series Although coprosterol and allocholesterol have not yet been recovered in the intermediary metabolism it was thought to be possible that the bile acids originate from sterols of the coprosterol-series Indeed in our^{130, 134} experiments on dogs with bile-fistulas the injection of allocholesterol and coprosterol increased the output of bile acids However, in dogs the amount of bile-acids produced daily was found to be so great, namely, about 2 gm, that the bile-acid formation must originate from a biological synthesis of the sterol-skeleton in the liver and not from a metabolic transformation of sterols already existing in the body The results of our experiments were confirmed by Schonheimer¹¹⁸ and his coworkers by adding deuterium on the double bond of cholesterol and feeding this deuterium containing cholesterol to animals The bile acids produced afterwards in the organism did not contain deuterium Thus we may assume that cholesterol absorbed or synthesized in the metabolic processes is excreted as unchanged cholesterol in the bile and in the intestines There cholesterol is transformed for the most part into coprosterol and probably undergoes a bacterial destruction to an unknown extent The ability of bacteria to destroy organic ring compounds is one of the most important facts in the equilibrium of the organic

world. Thus the uni-cellular organism prevents the preponderance of cyclic organic compounds, which are synthesized by higher plants and animals, over aliphatic substances in nature. The presence of certain bacteria in the bowels therefore is wisely provided for in all animals.

The ability of the intestine to excrete cholesterol is not the same in all animals. The herbivorous animals cannot excrete cholesterol in noticeable amounts although they are able to absorb animal cholesterol experimentally added to their plant food. Therefore, atheromatosis might be produced experimentally by feeding cholesterol to herbivorous animals. The question arises, which kind of sterols is absorbed in animal and human bodies? The experiments of Schonheimer¹¹⁶ and his coworkers demonstrate that neither herbivorous nor carnivorous animals absorb plant sterols. Only small amounts of ergosterol are absorbed. It is a noticeable fact that dihydrocholesterol, although it is formed in the intermediary metabolism and excreted in the intestines, is not reabsorbed. Cholesterol is the only animal sterol which undergoes absorption from the intestines. It is excreted in the bowels and reabsorbed to a large extent.

This marvelous selective absorption of sterols, unexplained in its mechanism, is of great importance for the sterol metabolism, protecting the body against an accumulation of sterols. The fact that cholesterol is synthesized in the metabolism prevents a deficiency of cholesterol in the organism due to an unsatisfactory absorption. In regard to the excretion, however, diseases may originate from an accumulation of cholesterol due to an unsatisfactory discharge.* This matter of clinical interest will be discussed later on.

The function of cholesterol itself in the metabolism is rather doubtful, although its wide occurrence in the animal kingdom is supposed to give a hint of its necessity. The main function of cholesterol is indicated in the fact that cholesterol and cholesterol esters are present in a constant percentage in every lipid mixture occurring on the surface or within the cell. Cholesterol is a hydrophobic colloid while the monoaminophosphatides like lecithin are hydrophylic colloids. The diaminophosphatides occupy a middle position between the two so far as their behavior towards water is concerned. The correct mixture of the lipoids in the cells depends on the presence of an adequate amount of cholesterol. Thus one of the important functions of cholesterol is seen to result from its physical properties, especially in regard to the equilibrium of the lipid mixture, which controls the exchange of fluid as well as the exchange of fat-soluble material in the cell.

Some authors attach significance to the fact that cholesterol neutralizes hemolytic substances, for example saponins, different glycosides, and animal venoms. To accomplish this the double bond and the hydroxyl group in the sterol molecule must be available. Esters and saturated sterols exhibit

* Bareda¹¹ proved that a clinical tolerance test by feeding cholesterol in oil and examining the serum cholesterol after a certain time gives unsatisfactory and not uniform results because the test depends on too many uncontrollable factors.

no anti-hemolytic efficiency. In a similar way cholesterol is supposed to be effective against some of the bacterial toxins. This conception is based on its action in vitro against tetanus toxin. Furthermore, it is observed that in most febrile infectious diseases blood cholesterol is reduced at the climax and also in the terminal stages of infectious diseases. It may be admitted, that while cholesterol forms insoluble addition products with anti-hemolytic substances, like tetanus toxin, in vitro, most of these substances, or reactions occur neither in normal nor in the diseased body. The claim then, that the main function of cholesterol must be a detoxifying one is not satisfactorily proved.

Hypotheses referring to the function of cholesterol are as numerous as they are fragile, so that the mention of a new hypothesis may be presumptive. The presence, however, of dihydrocholesterol in the tissues, as discovered by Schonheimer¹¹¹ can be explained by the assumption that there is an oxidation-reduction system in the body within which cholesterol-dihydrocholesterol plays the same rôle as succinic and fumaric acid do in an already known system of this kind.

The cells in the body break down and are rebuilt. In this process cholesterol becomes available and is needed. In addition to its metabolic utilization cholesterol is synthesized, excreted and accompanies neutral fat wherever fat is transported in the body. The concentration of cholesterol in the blood, therefore, depends on these different occurrences, so that an increase or decrease of cholesterol and cholesterol esters in the blood is not due to a one uniform cause.

Hypercholesteremia, whether due to cholesterol esters or to free cholesterol, is a symptom which indicates that the excretion of cholesterol does not keep pace with the endogenous and exogenous supply. Simultaneously with the symptom of hypercholesteremia, cells appear in different organs filled with lipids which are mainly sterols. These cells, which are called foam-cells, according to their appearance, or xanthoma cells according to their content, may after some time give up their cholesterol to the blood. There remains a granulomatous scar tissue consisting of giant cells, lymphocytes, and connective tissue. Before we enter into the discussion of the mechanism of the xanthoma formation, different clinical pictures of the xanthomatous diseases will be presented.

XANTHOMATA OF TENDONS AND TENDON SHEATHS

Case 1 R. S., a 65-year-old Jewish widow, noticed first the appearance of "burning lumps" on the knuckles of the third finger of each hand at the age of 35. When 55 years of age, similar lumps developed above both heels, and at the age of 62 a small node appeared on the right elbow.

She stated that a tumor of the uterus and both ovaries had been removed when she was 42 years old. She had gained much weight after the operation. She had been married three times, and had no children.

One brother had small but similar lesions on his fingers.

She was an elderly obese woman of the matron-type, not icteric. She had no

FIG 1 Case 1 Xanthomatous nodules of the tendon and tendon sheaths of the hand

FIG 2 Case 1 Xanthomatous nodules on both Achilles tendons

xanthelasma Liver and spleen were not palpable In the extensor tendons of both third fingers were circumscribed xanthomata measuring about 3 by 6 cm movable only with movement of the tendon in the region of the phalangometacarpal joint There was another small node on the fifth finger of the left hand and large xanthomata in the region of both Achilles tendons

Changes in the right knee joint, clinically and roentgenologically were characteristic of osteoarthritis, but no cystic bone lesions were present The patient was admitted to the hospital on 10/21/35

The following table gives the cholesterol findings in the blood serum

| | Serum Total Cholesterol | Free Cholesterol | Cholesterol Esters |
|----------|----------------------------|---------------------|-----------------------|
| 10/22/35 | 360 mg % | 200 mg % | 160 mg % |
| 10/29/35 | 368 | 240 | 128 |
| 11/7/35 | 347 | 191 | 156 |
| 11/19/35 | 351 | 187 | 164 |
| 11/26/35 | 345 | 148 | 197 |
| 12/2/35 | 338 | 158 | 180 |
| 12/17/35 | 420 | 200 | 220 |
| 1/15/36 | 388 | 198 | 190 |
| 4/17/36 | 394 | | |
| 6/2/36 | 440 | 124 | 316 |
| 7/9/36 | 423 | 163 | 260 |
| 9/10/36 | 390 | 70 | 320 |
| 11/13/36 | 364 | 113 | 251 |
| 2/20/37 | 284 | 100 | 184 |

A cholesterol-free diet was begun on 10/22/35 and continued until discharge on 11/29/35 Thyroid extract was administered as follows from 11/20/35, gr 1, b i d , from 11/20 to 11/29/35 gr II, t i d The thyroid was discontinued on 11/29/35

A small subcutaneous nodule appeared below the right knee cap during the diet treatment A biopsy from the node in the tendon of the third right finger showed the xanthoma to be intimately connected with and situated between the fibers of the tendon The section was composed of dense interlacing cellular strands and bands of collagenous tissue interspersed by innumerable varying sized groups of large foam cells Among these swollen xanthoma cells were occasional binucleated cells and rare mitotic figures There were no large giant cells

A smear from the first specimen showed many cholesterol crystals Analysis of dry tissue total cholesterol 9 mg per cent, total phospholipids 11 mg per cent

There was no recognizable change in the size of the lesions of the tendons during the period of cholesterol-free diet, which, however, the patient did not follow strictly Small xanthelasma-like yellow lesions in the skin of the nose at the site of the pressure of her eye-glasses appeared in December 1936

Case 2 R S, a 55 year old salesman, brother of Case 1, had noticed nodes on his knuckles for several years He had never been seriously ill and had no complaints

He showed a small xanthoma on the extensor tendon of his right fourth finger at the first interphalangeal joint He also showed circumscribed swellings of both Achilles tendons, 4 by $\frac{1}{2}$ cm The liver and spleen were not palpable

Discussion In 1879, Calcott Fox³⁹ in England and Carry²⁷ in France first described patients suffering from xanthomata of the tendon sheaths

The patient described was a member of a family which had suffered from so-called "gout" for three generations. The diagnosis of "gout" was previously made in the girl described, although at the age of seven she had yellowish xanthomata plana in addition to the tendon sheath nodules. The

FIG 3 Case 1 Histological picture of xanthoma cells in an excised tendon xanthoma of the hand

tendon sheath xanthomata are named the "gout form of xanthomata" even in later publications and textbooks. "Gout form" is a misleading term in these cases. True gout is due to a retention of uric acid and a deposit of its sodium salt in the gaps of connective tissue leading to nodules as the result of inflammatory reactions. Xanthomatous nodules are not produced by a deposit of cholesterol outside the cells, but by a disease of certain cells which contain cholesterol intracellularly. These cells undergo destruction due to their abnormal contents, and a granulomatous scar remains. Besnier called such a new growth "Xanthoma en tumeur." In 1882

Startin¹²⁷ reported six cases. In 1889 G. Lenzen and K. Knauss⁶² presented the first good pictures of such a patient in Virchow's Archiv. Brachet-Monnard,²⁰ Poensgen,^{89, 90} Balzer,¹⁰ Richter,⁹⁹ Lowe,⁶⁵ Arning and Lippman,^{6, 7} Ganat,⁴³ Ochs, Schmidt,^{107, 108} Schonheimer,¹¹⁵ Buerger,²⁵

FIG 4 Case 1 Cholesterol crystals in a softened part of a tendon xanthoma

Raeder,⁹⁶ Wile,^{156, 157} and many others described such cases. In the surgical literature Beekman,¹⁵ Brochard,²¹ Buxton,²⁶ Janick,⁵⁵ Dean Lewis,⁶⁴ Romiti,^{99a} Ragins,^{96a} F. Young and C. T. Harris,¹⁵⁹ emphasized the fact that xanthomata of the tendons are part of the tendon. Thus they cannot mechanically be separated from the tendon.

One of the tendon sheath xanthomata of our Case 1 was excised by Dr. Levenson for chemical analysis. The nodule could only be partially removed because the tumor was a part of the tendon of the third finger of the right hand.

Comment Sister and brother (Case 1 and Case 2) are elderly persons

In the sister the first tendon sheath nodules developed at the age of 35, the tumors on the Achilles tendons at the age of 55. The brother first noticed nodules on his hands at the age of about 40. The name "xanthoma juvenile" sometimes used in the literature for the xanthomatous tendon sheath is therefore not justified, although in many cases the development starts in

FIG 5 Case 2 Xanthomatous nodules of the tendon and tendon sheaths of the hand

the first years of life and even a congenital case has been reported. It is noteworthy that both our patients showed no other xanthomata of the skin although the tendon sheath xanthomata had been present for almost 30 years. The pinhead sized xanthelasma at the pressure point of the spectacles on the nose developed only recently.*

Histological Findings The main piece of tissue consisted of young fibroblasts and granulomatous tissue. This granulomatous tissue in which giant cells were found, invaded the normal tendon. Large cells with one or two nuclei were scattered throughout the nodule. These cells with a foam-like opaque protoplasm (foam cells) contained fat, cholesterol and cholesterol esters and monoaminophosphatide. The foam cells are found massed in the reticular tissue. They are supposed to develop from reticulum cells and histiocytes. The characteristic picture of a xanthoma, where it may be encountered, consists of scattered or aggregated large foam

* While this paper was in press, two papers appeared, one by L. van Bogaert, H. J. Scherer, and E. Epstein^{19a} with the title "Une forme cerebrale de la cholesterinose generalisee" and the other by E. Epstein and K. Lorenz^{25a} describing a similar case. These cases of van Bogaert, Scherer and Epstein showed severe neurological disturbances, ataxia, atrophies of different groups of muscles, disturbance in speech. Later on bulbar symptoms and flaccid paralysis of all extremities developed. The neurological symptoms began at the age of 12, progressed until the age of death, of 40 years. At the age of 33 only tendon xanthomata developed. Excellent histological pictures show foam cells and deposits of cholesterol crystals in the central nervous system. None of our cases with tendon xanthomata (1, 2, 7, 9, 10, 11, 12, and 13) showed any psychic or neurological abnormalities. The cases of van Bogaert showed normal and high normal serum cholesterol like our cases 2 and 10. The combination of central nervous system xanthomatosis and tendon xanthomata has not been described until now.

cells occurring in granulomatous tissue with fibroblasts and exudate cells or in old connective scar tissue

One area of the excised nodule, the size of a pinhead, was softened. Microscopically the yellow detritus showed typical cholesterol crystals and a few needles, probably cholesterol esters.

Chemical Findings The cholesterol content in the serum of Case 1 was never extremely high. However, figures above 400 were observed. Our early observations on this patient showed an inverse ratio of cholesterol-cholesterol esters. During the period of the cholesterol-poor diet, a normal ratio was restored but the total cholesterol remained at the same level, despite a cholesterol-poor diet taken over a long period of time. The brother, who had smaller nodules, exhibited high normal total cholesterol but an inverse ratio of cholesterol-cholesterol esters. In the cases of tendon xanthomata described in the literature, the total cholesterol values are very high and the cholesterol esters especially are increased. The inverse ratio of cholesterol-cholesterol esters suggests an involvement of the liver although clinical signs of hepatic disease are absent. Neither patient was ever jaundiced. It is significant that despite the patients' ages no unusual signs of vascular disease were found.

‡ In this and in most of the later described cases of xanthomatous diseases, phospholipids are determined quantitatively. Monoaminophosphatides (lecithin-cephalin) and diamminophosphatides (sphingomyelin) are determined separately by our new method (Thannhauser and Setz¹³⁵). Up to the present time the phosphorus value obtained using Bloor's method was multiplied by 25 and the figure thus obtained designated as lecithin. However, the so-called lecithin value comprises the monoaminophosphatide (lecithin-cephalin) and diamminophosphatides (sphingomyelin). Not only are these substances notably different in their chemical constitution, but also in their physiological significance. With our method of precipitating the sphingomyelin complex as Reinecke compounds, and separating and weighing the sphingomyelins, it is possible to determine sphingomyelins gravimetrically and to evaluate the rest of the formed total lipid phosphorus as lecithin and cephalin. Using serum from patients suffering from xanthomatous diseases, this method demonstrates whether an increase of cholesterol in the serum and tissue is accompanied by an increase of monoaminophosphatides (lecithin-cephalin) or by an increase of diamminophosphatides (sphingomyelin) or by a simultaneous rise of all three lipids.

In the serum of Case 1 the total phospholipids were increased. It is shown that the increase of phospholipids results mainly from a rise in the monoaminophosphatides (lecithin-cephalin). The sphingomyelins show only a small rise. In the analyzed tissue of the tendon sheath xanthoma, there was considerable increase of cholesterol and monoaminophosphatides but only traces of diamminophosphatides could be detected. These findings demonstrate that in the examined case an increase of sterols in the serum

as well as in the tissue is combined with an increase of monoaminophosphatides (lecithin-cephalin) but not with an appreciable increase of sphingomyelins. The physiological significance of this finding is unknown, but clinically it is important that the xanthomatous diseases show, in addition to the outstanding symptoms of increased cholesterol in serum and tissue, increased monoaminophosphatides, while in Niemann-Pick's disease the outstanding finding is increased diaminophosphatides (sphingomyelin) (E Klenk¹³)

XANTHOMA TUBEROSA

Case 3 Female of 40 years had known she had diabetes for two years. Had taken no special diet. Sugar excretion was always around 1 per cent (10 to 20 gm) daily. She noticed peculiar "warts" of yellowish color on both elbows five years previously. Blood examination showed slight lipemia. On both elbows there were typical xanthomata tuberosa. She became sugar-free on diet, but the tuberous xanthomata did not disappear. Total cholesterol 570 mg per cent.

FIG 6 Case 4 Xanthomata tuberosa on both elbows

Case 4 The patient is a 30 year old physician suffering from chorioretinitis of the disseminated type, affecting both eyes. He had had difficulty with his vision for three years. Despite search, a definite etiology could not be found. At almost the same time he noticed small lesions about the elbows, knees and buttocks which were diagnosed as xanthomata tuberosa. His main complaint was fatigue for the previous three years. He had no fever, no loss of weight. His appetite was good and he carried on his profession satisfactorily. Two children were living and well. Physical examination revealed no vascular disease. Blood pressure 110 systolic and 90 diastolic. Urine findings negative.

On both elbows there were xanthomata tuberosa. The pea-sized xanthomata had a yellow color and marked hyperkeratosis on the top of the lesions. Similar lesions were found on the knees and on the buttocks. No other xanthomata were observed. Mucous membranes were free.

The creases on the palms of both hands were yellow, of a carotene-like color. His blood serum showed the same color due to carotinemia. Quantitative determination of carotene was not carried out at this time.

Blood sugar (fasting) 86 mg %
 Sugar tolerance curve, 7/7/36 Fasting 86 mg %, ½ hour 154 mg %, 1 hour 102 mg %, 2 hours 78 mg %, 3 hours 53 mg %, 4 hours 93 mg %

This rather flat tolerance curve does not suggest a latent diabetes

Comment We have thus far considered only simple forms of what we consider to be xanthomata tuberosa. The above described nodules of the tendon sheaths as well as xanthomata multiplex disseminata, which will be illustrated later, are erroneously designated as xanthomata tuberosa. Tuberos xanthomata are nodular elevations of the skin. The nodules are usually observed isolated, not confluent or aggregated in small groups. The shape is irregular and they may vary from pea size to the size of a chestnut. Their favorite location is the extensor surface of the arms, especially the elbows, or on the buttocks. The surface usually shows hyperkeratosis and is of yellow or carrot-like color. Xanthomata tuberosa and xanthomata disseminata which are entirely different in size, shape, color and localization are generally confused in the literature. The mucous membrane and larynx are rarely involved in tuberos xanthomata in contrast to the xanthomata multiplex disseminata in which lesions almost always arise simultaneously in the mouth and larynx.

The reason for this confusion may be due to the fact that the histological findings are identical in both xanthomata tuberosa and xanthomata disseminata despite the fact that appearance and localization are clinically entirely different. In both lesions we find foam cells, i e, cells with one or two nuclei, “Touton giant cells”. The amount of fibrous tissue which is found in the nodule surrounding the foam cells varies according to the age of the xanthomatous nodules. In later stages only granulomatous scar tissue may be found. There is no sign of inflammation or vascularization around the nodules on the skin and no papule or pustule formation. This is important in differentiating between xanthomata tuberosa and the eruptive form of papulo-pustular lesions which occur in severe diabetes and symptomatic hypercholesteremia.

Xanthomata tuberosa may be combined, as in Case 3, with mild diabetes. In these cases of rather mild diabetes the lesions of xanthomata tuberosa (which do not itch) may be the expression of a similar xanthomatous eruption in the pancreas. In 1921 Wijnhausen¹⁵⁴ was able to verify such a coincidence by operation. In his patient xanthomata tuberosa were noticed

34 days before sugar was found in the urine. Frequent attacks of ileus, as in bowel obstruction, accompanied by fever were observed. Operation one year after the onset of the symptoms revealed chronic pancreatitis and tuberous xanthomata in the pancreas. The patient recovered from the operation. The diabetes and the tuberous xanthomata of the skin may be considered the result of the same disease, i.e. xanthomatosis, affecting the skin and pancreas simultaneously. This suggestion has also been mentioned by Rowland.¹⁰¹ As early as 1880 Gendre⁴⁵ reported the case of a patient who had been suffering from mild diabetes and tuberous xanthomata for 10 years. "Malgré la présence du diabète sucré datant de dix ans ce cas ne peut pas être rangé parmi les xanthomes diabétiques."

The eruptive form of papulo-pustular xanthomata, the so-called xanthomata diabeticorum, is entirely different in etiology from the xanthomata tuberosa. Xanthomata diabeticorum are the sequel of a severe diabetes mellitus in the course of which lipemia and hypercholesteremia occur, occasionally producing the itchy papulo-pustular eruptions which appear and disappear.

I should like to emphasize further the importance of differentiating between xanthomata tuberosa and xanthomata disseminata because the visceral organs involved may be predicted by the kind of skin lesions present. Xanthomata tuberosa and plana may be combined, as we shall see later, with endocardial and vascular xanthomata as well as with hepatic and pancreatic disease, while xanthomata disseminata is found with xanthomata of the bones and lungs, xanthomata of the brain and diabetes insipidus.

Serum Chemistry The serum of a patient with xanthomata tuberosa shows high total cholesterol values largely due to increased cholesterol esters. The cholesterol-cholesterol ester ratio is normal or changed in favor of the esters. The monoaminophosphatides (lecithin-cephalin) are markedly increased. The diaminophosphatides (sphingomyelin) are also a little higher than normal but the monoaminophosphatide-diaminophosphatide ratio shows that the increase of total phospholipids is mainly due to the increase of lecithin-cephalin. The glycerides are also considerably increased. The increase of the monoaminophosphatides and glycerides simultaneously with the cholesterol is to be considered a fact evident from many observations.

"FORME FRUSTE" OF XANTHOMATOUS DISEASES

Case 5 Mrs. F., 55, main complaint fatigue. For many years easily tired, very active in the household. Physical examination. Mentally quick, haggard lady. The color of her skin is brownish, like a tan (has not exposed herself to sunlight). Both palms of hands and feet and especially the creases of the hands show xanthosis, that is, a yellowish carotin-like color. Sclerae normal color. There are no abnormalities of the inner organs discovered, no signs of hypothyroidism. Urine and blood normal. Basal metabolic rate, minus 10 per cent, blood sugar 85 mg per cent, bilirubin, van den Bergh 0.5, icteric index 11.

| | Total Cholesterol | Free | Esters | Total P Lipid | Diaminophos Sphingomyelin | Monoamino-p Lecithin-Cephalin | Fat |

| After cholesterol poor diet | 276 mg % | 75 | 201 | 290 mg % | 81 mg % | 209 mg % | 389 |

Case 6 E de S, 48 years Family History Diabetes in several members of his ancestry Patient has six healthy children Patient reports that 10 years ago he had a trace of sugar in the urine Sugar disappeared without keeping to diet Six years ago he was examined in Paris and hypercholesteremia was found without other symptoms Total cholesterol at this time was 455 mg per cent Four months later, after a diet poor in fats, the total cholesterol was 320 mg per cent Patient kept on this diet for six years Cholesterol determination repeated several times during the past year showed values of total cholesterol around 200 mg per cent Basal metabolic rate normal on several occasions

The main complaint of the patient is fatigue He is sometimes depressed and feels uneasy He lives in the tropics now, has to be very active in his business His mental agility is quick, in contrast to his physical fatigability

Physical findings Man of normal figure, no signs of hypothyroidism The skin exhibits xanthosis on the trunk as well as on the extremities (see case 4), especially the palms of the hands and feet and the creases on the palms show a yellowish carotene-like color The lungs are normal Heart is normal in size, systolic murmur at aorta Blood pressure 135 systolic and 85 diastolic Liver and spleen not remarkably enlarged Blood and urine normal Blood sugar 102 mg per cent, bilirubin (Van den Bergh) 0.5 mg, icteric index 20

We report these cases as "forme fruste" of xanthomatous diseases because they have the same features as patients exhibiting xanthomata tuberosa (hypercholesteremia, xanthosis (carotinemia), inclination to mild diabetes) but no skin xanthomata These patients are often diagnosed as hypothyroids because they exhibit physical fatigability, high blood cholesterol and sometimes basal metabolic rates on the lower borders of normal In contrast to patients suffering from hypothyroidism, these patients are mentally very alert, they are not anemic, they perspire easily and have a smooth skin They are not slow in their activities, but they fatigue easily The cases reported by Edelmann^{34a} with xanthosis, fatigability, diffuse pains in muscles, complaints of irritability of the gastrointestinal tract, belong to this group We determined the carotene content of the serum quantitatively in a case which we have seen recently and found 0.4 mg per cent (normal 0.05 to 0.1 mg per cent) We believe that the forme fruste of xanthomatous diseases, characterized by hypercholesteremia, xanthosis and caroti-

nemia, associated with fatigability and inclination to mild diabetes, is seen not infrequently if distinguished from hypothyroidism

XANTHOMATA TUBEROSA AND PLANA AND TENDON XANTHOMATA

We were fortunate to discover an entire family suffering from xanthomata of the skin as well as of the tendon sheaths G K, a female child (Case 9), aged 11, was observed at the Children's Hospital We are indebted to Dr Blackfan and Dr Diamond for the privilege of seeing this child and for the opportunity to study the entire family, whose case histories follow

FAMILY TREE OF FAMILY K

Case 7 Mr I K, 50 years old, male, Jewish plumber, noticed painless swellings on knuckles of both hands when he was about 30 years old. During the last 5 to 10 years he also noticed swellings develop on both heels. Two to three years ago, he first suffered from attacks of substernal pain which were diagnosed as angina pectoris and responded to treatment with nitroglycerin.

He was the father of four children, all of whom showed evidence of xanthomatosis (see family tree), his mother had brown swellings on the eyelids, one sister (Mrs Ch, Case 13) had xanthomata of tendons, another sister is supposed to have xanthelasma.

He was moderately obese, not jaundiced. His eyelids showed no xanthelasma. Lungs and heart were found to be normal on physical examination. Electrocardiogram normal. Liver and spleen not definitely enlarged.

On the third, fourth and fifth fingers of both hands, xanthomata, movable with the tendons on the extensor side, were visible, most pronounced on the first interphalangeal joint. Small nodes were present in the olecranon region. Extensive swellings in the region of the lower third of both lower legs, bulging posteriorly and laterally in the region of the Achilles tendons. These swellings were firm, non-tender, larger than those in any other member of his family, measuring 8 by 3 cm.

Case 8 J K, a 47-year-old Jewish housewife, first seen October 27, 1936, noticed brownish swellings on both upper eyelids at the age of 23, after her first child was born. When she was 40 years old these lesions had grown considerably and similar lesions had appeared on both lower lids also. No history of serious illness in the past.

Family history See family tree

She was a markedly obese woman without icterus. There were characteristic xanthelasmata in both upper and lower eyelids, the smaller measuring 3 mm in diameter, the largest 5 by 20 mm, of soft consistency, elevated 1 to 2 mm above the level of the skin. No tumors of any tendons were palpable. Liver and spleen were not palpable and not enlarged on percussion.

On a reduction diet, she lost 31 pounds in seven months. There was no change in her xanthelasma.

Case 9 G K, 11 years old, Jewish schoolgirl (daughter of J K) noticed painless nodes appear in the region of both heels at the age of seven. One or two years later similar lesions were seen on the knuckles of several fingers and there was also involvement of the skin of the knees and elbows.

She was an underdeveloped, undernourished, intelligent girl. The xanthomata of the skin were round, brownish-orange colored, flat lesions, 3 to 4 cm in diameter, with somewhat pronounced margins and sharp borders. The center of these lesions was darker and slightly depressed. Similar, although much smaller tuberosus skin lesions were visible in the gluteal folds and flexor aspect of the knees. Besides there were xanthomata of the extensor tendons of the third and fourth fingers of both hands, and larger xanthoma nodes in both Achilles tendons. Liver and spleen not felt. No jaundice. (Figures 7, 8, 9, 10, 11)

The round intradermal lesion on the left elbow was surgically removed and proved to be in intimate contact with the tendon of the triceps muscle. Tissue analysis of the dried lesions, freed as much as possible from subcutaneous fat, showed no sphingomyelin. The total phospholipid content of the dried substance was 12.7 mg per cent. Total cholesterol of the dried substance was 13.1 mg per cent.

FIG 7 Case 9 Xanthomata tuberosa and plana on both elbows and both knees

Case 10 S K, 22-year-old Jewish girl, daughter of J K, was seen December 7, 1936. She had no complaints but had seen and felt nodes on her heels for two years. She had been obese as a child.

Patient showed slight bulging of the region of the Achilles tendons on both sides, 5 cm distant from the floor, as the only demonstrable abnormality.

Case 13 Mrs Ch (sister of Mr K), 51 years old, Jewish housewife (aunt of the 4 K children) was seen April 17, 1937 She had noticed painless lumps on knuckles of various fingers at the age of 37

FIG 9 Case 9 Xanthomatous nodules on both Achilles tendons

FIG 10 Case 9 Xanthoma planum, Sudan staining

FIG 11 Case 9 Xanthoma planum xanthoma cells

She was moderately obese, showed no icterus, no xanthelasma of the eyelids. There were xanthomata of three fingers of each hand, predominantly in the region of the phalango-metacarpal joint, also xanthomata in both Achilles tendons, 2 cm in diameter and small superficial tuberos nodules in the region of both elbows. Liver and spleen were not enlarged.

Comment Heredity Case 8 has unusually extensive xanthelasma on both eyelids. Several members of the father's (Case 7) family have tendon sheath xanthomata. All the children of this couple were examined and all were found to have tendon sheath xanthomata. The youngest child, Case 9, has xanthomata plana (xanthelasma), xanthomata tuberosa and tendon sheath xanthomata. It is evident from different cases described in the literature (Torok,¹⁸⁸ Raeder,⁹⁶ Wile and Dumehing,¹⁵⁷ and from the family tree of this family that heredity is dominant.

Case 9 (11 year old girl) has different kinds of xanthomata of the skin. Later we shall discuss the fact that histological examinations of all kinds of xanthomata reveal a more or less uniform histological structure consisting of foam cells and granulomatous tissue. Because the gross appearance of xanthomata of the skin is different in shape and in color, we have to deal with a nomenclature which describes the different gross appearances of the skin but not different diseases.

Xanthomata plana or xanthelasma are flat xanthomata of carotene-like color or that of chamois leather. In the child, Case 9, xanthomata plana were found on both elbows * both knees and buttocks. In addition she had xanthomata tuberosa on both elbows, on the buttocks and on the skin of the heels overlying the tendon tumors. Temporarily when she was first observed and once later she even had an eruptive papulo-pustular form of xanthomata on both arms and legs. These eruptive lesions appear and disappear and up to the present time have been observed only on patients suffering from diabetes mellitus.

Later we will show that the papulo-nodular eruption known as xanthomata diabeticorum may occur without diabetes not only in cases such as that just described but also in patients with jaundice and xanthelasma due to xanthomatous liver cirrhosis with a very high serum cholesterol.

We follow Montgomery and Osterberg ⁷⁶ in separating xanthomata multiplex disseminata from the discussed manifestations of xanthomata of the skin. The disseminated multiple xanthomata does not differ in its histological structure but differs in shape, color and especially in localization, distribution and diagnostic significance. We were unable to find a single case in the literature where disseminated multiple xanthomata of the skin were found in the same patient coincidentally with xanthomata plana and tuberosa, or in patients with tendon sheath xanthomata. But, as we observed in the members of the K family and other cases cited in the literature, xanthomata plana as well as xanthomata tuberosa are very often combined with xanthomata of tendons.

DISCUSSION OF COINCIDENCE OF XANTHOMATA PLANA AND XANTHOMATA OF TENDONS WITH XANTHOMATOUS INVOLVEMENT OF HEART, BLOOD VESSELS, AND LIVER

In 1879, Calcutt Fox,³⁹ in the first description of tendon sheath xanthomata combined with xanthomata plana, found the mitral valve involved with xanthomata. Poensgen (1887)⁸⁹ describes tendon sheath xanthomata, xanthomata plana and tuberosa with aortic involvement in a boy of eight years. Lenzen and Knauss (1889)⁶² described and showed a picture of an 11-year-old girl, who, like our patient of the same age (Case 9), had xanthomata plana, xanthomata tuberosa and tendon sheath xanthomata. Their patient died from an intercurrent infection following operation. Autopsy

* We are indebted to Dr. Hilbert F. Day for the excision of one xanthoma plana on the left elbow. 1½ years after this excision there is no recurrence of the xanthoma in the scar.

revealed xanthomata on both pulmonic and mitral valves (patient exhibited intra-vitam unusually loud systolic murmurs) and xanthomatous patches in the pulmonary artery, but the aorta and left carotid showed a xanthoma of the intima simulating a neoplasm which almost occluded the lumen of the vessel. Both coronaries of the 11-year-old child also demonstrated xan-

FIG 12 Xanthomatous nodule of the intima of an artery (Microphotograph of Dr Timothy Leary of Boston)

thomatous patches the size of a pinhead. It is noteworthy that this patient had a sister with the same disease. Similar familial cases with involvement of the heart and the arteries in children are described by Arning (1910),^{6,7} and by Lowe (1910)⁶⁸ and then by Hess (1934)⁵¹. In all these cases the xanthomatous involvement of the endocardium and vessels was combined with tendon sheath xanthomata and skin lesions of xanthomata plana and xanthomata tuberosa. We should like to emphasize that in the literature, as far as has been able to be determined, not a single case is described where xanthomata multiplex disseminata was found combined with xanthomata of the endocardium and the vessels which we shall picture and discuss later.

At this point we should like to call attention to the fact that hypercholesterolemia is found where xanthomata plana, xanthomata tuberosa, and ten-

don sheath xanthomata are combined with vascular xanthomatous disease, while normal cholesterol values are found in patients suffering from xanthomata multiplex disseminata and xanthomatous bone diseases

Simultaneous involvement of the liver is rare in cases where xanthomata plana and tuberosa and tendon sheath xanthomata exist over a long period of time without jaundice. Later we shall show that jaundice is the initial symptom of xanthomatous biliary cirrhosis in the course of which (but only after a period of jaundice) the most impressive xanthomatous changes of the skin in the form of xanthomata plana or xanthomata tuberosa may arise. The spleen, the lymph glands and the lungs were not involved in this group of cases but these organs are involved in the group of xanthomata multiplex disseminata of the skin with xanthoma in the brain and the bones

XANTHOMATOUS BILIARY CIRRHOSIS

Case 14 Female, aged 35 years, wife of a farmer in Germany¹⁰⁴ One sister suffering from cholecystitis. Married, one healthy child. Patient noticed jaundice in January 1931, for the first time, no pain or other symptoms from the gall-bladder, stools clay-colored, urine dark, itching all over the body. The physician diagnosed gall stones and the patient was operated upon on April 7, 1931. The wall of the gall-bladder was very thick. A gland was found which was intimately connected with the gall-bladder (xanthomatous scar tissue) in the place where the hepatic duct branches. The liver was firm in consistency. There were no stones found and all the larger bile ducts were free of stones. The gall-bladder was removed. After the operation the jaundice increased. Patient grew worse. Treatment with diathermia and carbohydrate and insulin was without effect. Operation again considered by the physician. She was then first admitted to our hospital, November 19, 1931. Weight 52 kg, height 148, severely jaundiced. Several lesions of the skin from scratching. At that time no xanthomata or tuberosus xanthomata. Temperature between 37.1° and 37.9° C. Lungs. Normal vesicular breathing, no dullness. Heart. Normal size, no murmurs, blood pressure 140 systolic and 80 diastolic, pulse 76. Abdomen distended, umbilicus deformed. Liver enlarged, five fingers below the costal margin, very firm, surface smooth. Spleen enlarged, firm. There is a small amount of ascites. No *caput medusae*. Urine trace of albumin, no sugar, urobilin and urobilinogen strongly positive, bilirubin positive, sediment, few leukocytes. Blood 75 per cent hemoglobin, 3,600,000 red blood cells, 7,200 white blood cells, 1 basophile, 1 eosinophile, 1 stab form, 70 polynuclears, 27 lymphocytes.

Hospital treatment from November 19 to December 20, 1931. Carbohydrate-rich, protein-poor diet with 5 units insulin twice daily. Diathermia of the liver. Weight loss during this time 0.5 kg. From November 26 to December 8, very strong menstrual bleeding. On December 11, sudden rise in temperature to 39° C, fever continued for five days. Jaundice during the hospitalization was not changed, never evidence of complete obstruction. Never colicky pain. Discharge diagnosis Biliary liver cirrhosis.

Second admission to our hospital January 11, 1933. Patient reports that no marked changes have occurred since her hospital stay. The menstrual bleeding in the meantime was always excessive. She was inclined to bleeding from the gums and from the genitals apart from menstruation. She felt increasingly weak and without appetite. Stools were not completely acholic. Urine always dark. Physical examination. Weight 43 kg. Jaundice deeper brown. Liver, much larger than at the first admission, almost the whole abdomen is filled by the liver. Its border is

three fingers below the umbilicus Very firm, surface smooth, no nodules Spleen the same size as at the first admission, three fingers below the left costal margin No ascites was found at this time Surprisingly large lemon-yellow patches were visible on the green-brown jaundiced skin which had not been present the year before These yellow patches, varying in size from 1 to 10 cm, easy to recognize as xanthomata plana, were found around the eye-lids, on the nose and cheeks, on the abdomen

FIG 13 Case 14 Xanthoma plana on both eyelids, the nose and the face

and also on the scar from the operation On the arms both on the flexor and extensor surfaces and all over the body were extremely itchy papulo-pustular nodules Around the nodules was a small inflammatory zone of pink color which changed peripherally to bluish-red and finally to brownish The pustules did not contain fluid or pus but on opening, a soft tissue of yellowish color was seen Because these

FIG 14 Case 14 Eruptive form (papulo-pustular form) of xanthoma.

eruptions itched so excruciatingly they had been badly scratched and give the impression of an abraded vesicle with the formation of a crust. The nodules which were not injured by scratching healed without crust formation, but a dark pigmentation remained. Blood: 55 per cent hemoglobin, 2,600,000 red blood cells, 9,000 white blood cells, blood sugar 82 mg per cent. Bilirubin direct 14.1, indirect 8.1 Van den Bergh's units. Total cholesterol 657 mg per cent, free cholesterol 376 mg per cent, cholesterol esters 281 mg per cent. Urine: Albumin positive, sugar negative, urobilinogen strongly positive. After a period of strict vegetable diet without any animal cholesterol we noticed an impressive decrease of the total cholesterol, but the inverse ratio of cholesterol-cholesterol esters remained, which is according to Thannhauser and Schaber a sign of liver damage.

| | Total cholesterol | Free cholesterol | Cholesterol esters |
|-------------------------------------|----------------------|---------------------|-----------------------|
| February 1 | 657 mg % | 576 mg % | 81 mg % |
| February 14 (cholesterol free diet) | 406 | 314 | 92 |
| February 28 | 152 | 132 | 20 |

On a less strict diet which contained some animal sterol the patient showed after four weeks 296 mg per cent total cholesterol, 124 mg per cent free cholesterol, and 72 mg per cent cholesterol esters. Normal persons who eat a diet free of animal sterol do not change their blood cholesterol (Bareda¹¹). Within 28 days the total cholesterol in this patient's case decreased from 657 mg per cent to 152 mg per cent. These figures show that 20 gm of cholesterol disappeared from the blood if we take four liters as the normal amount of circulating fluid. During the vegetable diet period the sterols in the feces were isolated and determined following the technical methods of Schonheimer. The daily amount of sterol in the feces in the beginning of the diet was 1.26 gm, later it fell to 0.53 gm, and at the end of the diet to 0.827 gm. The attempt was made to isolate cholesterol, dihydrocholesterol and coprosterol quantitatively. Only traces of coprosterol were found but it was impossible to isolate free cholesterol or dihydrocholesterol from the feces during this period. This result is in conformity with the findings of Schonheimer. The sterol structure present in the feces while on the sterol-free diet consists apparently only of plant sterols. It is not evident how the 20 gm of cholesterol disappeared from the blood. Bacterial destruction of cholesterol in the feces may give an explanation for this important fact according to B. Ottenstein.

The patient grew gradually weaker. She again developed a high fever for the period of a few weeks. Her weight fell to 41 kg. She lost ground rapidly and died eight weeks after she left the hospital. A partial autopsy was performed. Prof. Aschoff, who examined the liver, found a marked cirrhosis and the same xanthomatous changes of the liver tissue which Chvostek described in his case of "xanthelasma and icterus" as xanthoma of the liver.

Case 15 (I am very much indebted to Dr. James Waring, Professor of Medicine of the University of Colorado, for the permission to publish this case.)

H. L., housewife, aged 32 years, born in Vienna. Entered Colorado General Hospital November 19, 1935, with the complaint of jaundice and weakness of four years' duration and of yellowish plaques distributed over the body, especially on the face and in the creases of the hands and feet, of about two and a half years' duration.

Past history Patient had measles at seven years, chickenpox at eight years. Never has had scarlet fever, mumps, whooping cough, rheumatic fever, chorea, or venereal disease. Menstrual periods started at 15 years, were regular every 28 days.

until spleen was removed two years ago Has not menstruated since No menopausal symptoms One child, nine years of age, a boy, living and well No other pregnancies In 1926, the appendix and one ovary were removed

Family history Mother, living and well, aged 58 years No tuberculosis contacts No history of cancer, diabetes, or Bright's disease No illness in family similar to patient's No blood dyscrasias, no hay fever, no asthma

Present illness The patient believes that she was feeling quite well until June 1931 At that time she first noticed that her eyes were yellow Shortly afterwards her skin became yellow, the urine highly colored and the stools grayish in color This jaundice gradually increased in intensity and was accompanied by much itching In September 1931, she consulted a physician in Boston who told her that she had gall stones and advised an operation, which was refused Patient's weight at the onset of her illness was 160 pounds In four months, that is at the time she consulted the physician in Boston, her weight had fallen to 132 pounds In March 1932, she consulted a physician in Cleveland who told her that she had an obstruction of the gall ducts and advised an operation which was again refused Meanwhile the jaundice had increased in severity and the itching was almost intolerable In April 1932, she came to Denver and consulted two physicians A diagnosis of obstructive jaundice was made and an operation advised At this time, she was told that she had a large liver The jaundice now showed some variation in intensity and the itching lessened but the patient complained of great weakness Around both eyelids, xanthelasma palpebrarum was noted In May 1933, she went to Memphis, Tennessee, where she was operated upon and her spleen removed, but there was no change in the condition following the operation No gall stones were found, but a narrowing of the common bile duct About a month before leaving Denver in May 1933, she first noticed yellowish deposits in the creases of her hands They came on gradually but were rather diffuse in distribution from the very onset, that is, they appeared on the face and on all extremities including both elbows at about the same time About the middle of 1934, she was quite sick with high fever, increase in jaundice and some delirium In May 1935, she was given a number of fever treatments at the Colorado Psychopathic Hospital The fever treatment did not change the condition of the patient

Patient was seen again by a doctor in Denver in August 1934 She now had yellowish plaques in the creases of the palmar surfaces of both hands They were each about 2 mm wide and slightly raised They were also present on the anterior surfaces of the elbows and on the elbow tips On the extensor surfaces of the elbows the plaques were enlarged patches and were much raised above the surrounding skin They were also present over the buttocks Progress from the fall of 1935 was gradually downward She had numerous persistent nasal hemorrhages and a little fever off and on much of the time The first nasal hemorrhage occurred about 1934, lasted about 10 hours and it is estimated that about a pint of blood was lost Since this time she has had a nose bleed of more or less severity about every six weeks Epistaxes lasted from six to ten hours and were controlled with difficulty She does not bruise easily and apparently had not had any petechial spots She showed marked susceptibility to respiratory infections which were severe and prolonged With one of these she had an acute suppurative otitis media on the right side She finally died July 1936, apparently of a typical coronary occlusion

Physical examination General appearance Her entire body is jaundiced, of a dusky bronze color with a tinge of yellow apparent The coloring is diffuse and fairly uniform with no distinct patches of pigment No deformity of bony skeleton or skull No discoloration of mucous membranes Head Small nodules apparent on upper eyelids and along the inner canthi The larger of these have been removed by her physician Eyes Some patchy congenital discoloration of the iris Left

pupil larger than right Pupils react to light and accommodation Consensual reflex present No nystagmus, exophthalmos, visual disturbances or fundal pathology Conjunctiva and sclera slightly yellow Visual fields grossly normal Mouth Posterior pharynx narrow with large hypertrophied tonsils from which no pus can be expressed Chest Organs apparently normal Diaphragm high posteriorly Heart No enlargement noted Sounds somewhat distant but no murmurs detected

FIG 15 Case 15 Xanthoma plana and tuberosa on the face, around the eyelids and the papulo-pustular eruptive form associated on the face

Blood pressure 110 systolic and 70 diastolic Peripheral vessels soft, pulse regular, rhythmic Abdomen Large operative scar The liver is palpable throughout most of the abdomen Liver is slightly tender along the left margin No nodules noted No fluid detected No bulging of the flanks Back and extremities No deformity, pain, or limitation of motion On both palms along practically all the flexor creases there are yellowish nodules about 3 mm above the skin On the extensor surface of

the elbow there is a large hyperkeratotic mass of the same character. Many similar nodules are distributed along the dorsum of the foot around the toes. Mucous membranes are free from xanthomata. Besides these tuberous and plain xanthomata, a nodular pustular eruption is to be seen, of the same appearance all over the body. There are papules which are excoriated by scratching. (In the photographs this eruptive xanthomata identical with the xanthomatous eruption in cholesterolemia during diabetes mellitus is clearly pictured.) Neurological: Gait and station essentially normal. Romberg negative. Muscular strength decreased. Ability to perform

FIG 16 Case 15 Enlarged liver

coordinated movements unimpaired. No ataxia, dysmetria, past pointing, athetosis, tremors, spasticity, rigidity, dysarthria, dysphasia, Holmes rebound phenomena or adiadochokinesis. Sensory examination essentially negative. No abnormal subjective sensations other than itching. Knee jerks, ankle jerks, biceps, triceps, radial, patellar reflexes equal and hypoactive, corneal reflex present, superficial abdominal reflexes absent. No Babinski sign or confirmatories. Cranial nerves intact.

May 2, 1935. No roentgen-ray evidence of pathologic changes in bones of skull, chest, pelvis, feet or hands. No definite defects in cranial bones, changes in sella turcica or metaphyses as described in Schuller-Christian's disease.

Urinalysis: color amber, slightly hazy, acid, specific gravity 1.022, trace of albumin, no sugar. Sediment contains a few pus and epithelial cells and many

bacteria, no casts or erythrocytes Blood examination Hemoglobin 10.2 grams, erythrocytes 3.2 million per cu mm, leukocytes 12,650, polymorphonuclears 80 per cent, lymphocytes 14 per cent, monocytes 4 per cent, eosinophiles 2 per cent Blood sedimentation $\frac{1}{2}$ hour 20 per cent, 1 hour 40 per cent Serological examination Wassermann test negative Eagle flocculation test negative

FIG 17 Case 15 Xanthomata tuberosa on both elbows

Electrocardiogram showed slight left axis deviation showing definite respiratory shift Basal metabolism rate, plus 8 Blood chemistry Sugar (dextrose) 84 mg per cent, total N P N 33, total cholesterol 400, calcium 10.60 Van den Bergh test 2.66 mg bilirubin per 100 ml blood, direct reaction Icterus index 22 Fragility of red cells normal

Case 16 E H, a 49-year-old Jewish widow, began to have severe itching all over her body at the age of 46. Shortly afterwards eruptions of a pustular character appeared, which bled after scratching. These lesions had been recurring for three years previous to admission. The patient lost 20 pounds in weight within the first year after the onset of the illness. She complained of weakness and had noticed that her urine was at times dark brown. Past and family histories revealed no significant data.

FIG 18 Case 15 Xanthomata plana on the palms and creases

When first seen she was icteric and the skin was covered with lesions of discrete varioliform character. They were less than 1 cm in diameter, on some of them the top was replaced by a crust and surrounded by an inflamed zone. They were fairly symmetrical in distribution but possibly more on back and abdomen than elsewhere. They were superficial and the old lesions represented by faint pigmentation, which persisted for some months (figures 20, 21, 22).

Heart and lungs essentially normal. Blood pressure 160 systolic, 90 diastolic. The liver reached two to three fingers' breadth below the costal margins, the spleen two

FIG 19 Case 15 Xanthomata tuberosa and plana and eruptive papulo-pustular form associated on both legs

FIG 20 Case 16 Eruptive form (papulo-pustular form) of xanthoma on the front of the body with enlarged liver and spleen

FIG 21 Case 16 Eruptive form of xanthoma (papulo-pustular form), on the back

FIG 22 Case 16 Histological picture of the eruptive (papulo-pustular) form of xanthoma
Notice that no xanthoma cells are seen

fingers' breadth below the costal margin Both were firm, smooth, non-tender No signs of portal obstruction were visible, including the absence of esophageal varices

The urine contained constantly 0.5 per cent albumin, increased urobilinogen and urobilin, occasional granular casts and rare red blood cells Icteric index 14 on admission, a year later when the icterus had subsided it was 4.5 and the indirect Van den Bergh reaction less than 0.5 mg per cent Non-protein nitrogen 39.6 mg per cent Red cell fragility normal Basal metabolic rate varied between plus 25 and plus 35 Blood sedimentation rate 93 mm in 1 hour (Westergren) Blood cholesterol 570 mg per cent

A year later the patient was put on a cholesterol free diet, following which regime the itching disappeared and the skin lesions diminished, but they did not disappear completely Patient was given thyroid, gr 1 daily, in addition to the cholesterol-free diet Within the last year small xanthelasma lesions developed on both upper eyelids She had several furuncles which had to be treated surgically Albuminuria and moderate hypertension remained unchanged as did the enlargement of the liver and spleen

Discussion and Comment The first patient (Case 14) died from hepatic failure due to chronic biliary cirrhosis, having been severely jaundiced for four years The xanthelasma developed two years after the onset The eruptive papulo-pustular lesions came and went During these years a pulsating angiomatous xanthoma developed in a tendon of the left little finger

Necropsy showed a severe cirrhosis with fat-loaded reticulum cells and foam cells scattered through the liver There is no question that the hepatic cirrhosis did not result from alcoholism or chronic infection of the bile ducts, but from the formation of xanthomatous tissue which led to connective tissue and scar formation, as in Chvostek's case

The second patient, Case 15, 32 years of age, died from a coronary thrombosis having been jaundiced for five continuous years The course of the disease was exactly the same as in case 14 At first there was painless jaundice accompanied by enlargement of the liver and spleen In both instances operation was performed because of a diagnosis of cholelithiasis but stones were not found In the second case the surgeon noticed thickened bile ducts but no histological examination of the bile duct was

made Cutaneous tuberous and plain xanthomata developed in both about one year after the jaundice was first noticed It may be emphasized that chronic jaundice in the usual biliary cirrhosis is not accompanied by the formation of xanthomata even after a very long period of jaundice In cases of ordinary biliary cirrhosis the cholesterol in the serum may be high and in cases of biliary cirrhosis with partial obstruction it may be very high, but no xanthomata develop The appearance of xanthomata during a prolonged jaundice suggests a special type of hepatic cirrhosis and bile duct involvement These are histologically identical with xanthoma cell formation in the skin

The total cholesterol in the serum of both patients was high and the ratio of cholesterol to cholesterol esters was inverted We attribute this inversion to the severe damage of the hepatic tissue The phospholipids in the serum of both cases were not examined We would expect in such a severe liver disease, in the light of experience gained from the separate determination of diamminophosphatide (sphingomyelin) and monoaminophosphatide (lecithin-cephalin), a low normal sphingomyelin but high lecithin and cephalin values

A very intensive eruption of papulo-pustular xanthomata was seen in all of these three cases The eruptive form of xanthomata changes in degree during the disease, because this form depends, in our experience, to a great extent on the cholesteremia

The patient (Case 15), a young woman of 32 years, died of coronary thrombosis Although an autopsy was not done, it seems very likely that the coronary thrombosis in this case was due to the same etiology which caused the xanthomata of the skin, liver and bile duct Especially since we learned from the cases reported in the literature that juvenile patients who exhibited xanthomata of the skin and tendon sheaths died suddenly from heart disease and autopsy revealed severe xanthomata formation on the valves, large vessels and coronaries

The third reported patient (Case 16), is alive and under our observation She differs from the two other patients in two points First, she is not constantly jaundiced At times she has a slight yellowish tinge to the sclerae, sometimes a real jaundice, and other times, as at present no trace of jaundice Secondly, three years after the onset of symptoms, she had only small xanthomata of the skin of both eyelids However, the main symptoms in the three cases are chronic enlargement of the liver and spleen, constantly high cholesterol values in the serum, and independent of the jaundice, itching eruption of nodular pustular xanthomata

It is astonishing that this form of xanthomatous disease of skin and liver with xanthomatous cholangitis is almost unknown, because it is never considered in the modern textbooks on medicine Yet this peculiar complex of symptoms and its underlying pathology have been described by classical authors We find it stated in some articles that Rayer in 1835⁹⁷ de-

scribed "plaques jaunâtres des paupieres" and that Addison and Gull in 1850¹ named the same disease "vitiligoidea planum et tuberosum" But nowhere in the modern literature are Addison and Gull credited with the full description of the symptom complex of skin xanthomata with a peculiar form of cirrhosis of the liver although in fact these authors did describe three patients with jaundice, xanthomata of the skin and hepatic cirrhosis in Guy's Hospital Reports, 1850 From the same hospital, Fagge,³⁶ Howes,³⁶ Murchison⁷⁹ and Pye-Smith^{94, 95} report similar cases in the Transactions of the Pathological Society with detailed autopsy findings and histological examinations In the French literature Bazin,¹² Hillariet,¹² Chambard,¹² in 1878 report similar cases with xanthomata and jaundice Besnier¹⁶ in 1876 describes tuberous xanthomata and plaques with liver, heart and arterial disease

The clinical description of Addison and Gull in 1850¹ is so important that one of the reported cases may be quoted verbatim to demonstrate the similarity to one of our reported patients (Case 15)

"Case of Eliza Parachute, aged 33, of middle stature, moderately well nourished, mother of six children, catamenia regular Her present illness began in 1848, she attributes it to fright, and to a blow received in the left groin whilst attempting to separate two men who were fighting Two days after this she became jaundiced, and had from time to time severe paroxysmal pains about the hypochondria, lasting for a day or two, the liver being also enlarged and tender Four months after the commencement of the jaundice (August 4, 1848) she was admitted into the Hospital under the care of Dr Hughes She remained in until September 26, and left much in the same state she was in when admitted There was at this time nothing complained of beyond itching and irritation of the skin common in jaundice The present affection began after the jaundice had continued 14 months, when she again came under the care It first appeared in the hands, spreading across the flexures of the joints of the fingers and palms Soon afterwards a yellowish patch of discoloration began near the inner canthus of the eyelid, and then a precisely symmetrical one at the same part on the opposite eyelid These patches are very slightly raised, and not obviously indurated, they have extended very slowly At this time the patches on the face existed as above described Along the ridges bounding the flexures in the palm and about the joints of the fingers, there were yellowish, opaque, irregular, and somewhat raised lines About the thumb, first joints of the fingers, and inner interior parts of the wrists, there is a gradual transition to a tubercular prominence of the affected parts, and some distinct tubercles exist on the elbow and knee"

In the same paper Addison and Gull¹ gave the first description of the eruptive form of xanthomata diabeticorum in a diabetic patient, in a wonderfully picturesque manner The pupils of Addison at the Guy's Hospital report the first anatomical findings in the liver, bile ducts and arteries Moxen (Trans Path Soc, 1873)⁷⁸ reports the case of a man 32 years of age, severely jaundiced for two years with two attacks of colic, xanthelasma on the palms, scrotum, back, ears, cheeks and lids He died of hemorrhage from a hepatic lesion The postmortem examination showed only hepatic cirrhosis, no gall stones

"The gall ducts throughout the organ were excessively wide so that on section of the liver their contents welled up in enormous quantity, being a white clear fluid, in strong contrast with the serum of the blood which was golden yellow. These dilated gall ducts had xanthelasma looking patches within them—that is, white opaque patches. The hepatic duct at the point of union of its two divisions was swollen from the pressure in it of a firm, tough matter making a little soft knot of the size of an almond around it and in its walls. The microscope showed only fibrous scar tissue in the thickening."

This is like the operative finding in our Case 14. Similar reports are found in the literature (Futcher,⁴¹ Weidman¹⁵⁰). The scar tissue in all these cases, which almost completely occluded one of the bile ducts, is granulomatous in character resulting from xanthomata patches lining the wall of the bile duct. Xanthomatous patches were found on the arteries, especially the aorta, on the trachea near the bifurcation, and one in the capsule of the small spleen. Hilton Fagge³⁶ reported in the same volume of the Transactions (1873, v, 242) a case of vitiligo (which has since received from Erasmus Wilson the more euphonious title of xanthelasma) with a pathological report by Dr. Howse. The patient was jaundiced for seven years continuously. Xanthomatous patches were found on the eyelids, hands, abdomen, lips, larynx and trachea, hepatic cirrhosis, enlarged spleen with a large number of minute white grains within it. The lungs and brain were normal. The left auricle, aorta and pulmonary artery and almost all the vessels presented a large number of yellow spots and patches.

"They were sharply defined and raised slightly above the level of the lining membrane of the vessel." "The nature of the growth appears to be essentially the same wherever it occurs, whether in the mucous membrane, on the tendons or on the skin. It appears to be a kind of universal atheromatous change. From wherever the sections are taken they show fine granular cells variously disposed amongst the fibrous tissue of the part affected. In the other growths they undergo still further degenerative changes becoming converted into lumps of calcareous matter, crystalline bodies, etc. Thus it would be a matter of indifference whether we should speak of the cutaneous disease as an atheroma of the skin or of the arterial affection as a xanthelasma of the aorta."

A third case with autopsy was described by a third physician of Guy's Hospital, Pye-Smith, at the same time,⁹⁴ in the Transactions of the Pathological Society 1873, p. 250. A woman 49 years of age had attacks of colic over a period of two years with intermittent jaundice but her urine was always dark. She showed xanthelasma only on both eyelids. She died of an intercurrent severe erysipelas. The postmortem examination revealed only one calculus in the gall-bladder but the biliary ducts were found to be much dilated. "Patches precisely like those in the eyelids and hands were found on the surface of the spleen and in the mucous membrane of the dilated hepatic ducts." The liver showed a slight degree of interstitial cirrhosis. "The patches in the ducts looked just like atheroma in the artery with which condition indeed, they correspond histologically."

Already in 1882, 23 similar cases with jaundice and xanthelasma were

collected and described by an English Committee for investigation of xanthomata (J Hutchinson, A Sangster and H R Crocker⁵⁴) The question that xanthomata exist without liver disease was decided by the report of cases of xanthomata plana and tuberosa without jaundice In 1884, Balzer,¹⁰ referring to three patients with liver disease and xanthomata in the French literature, believed that he proved an infectious etiology of the disease but this was never confirmed In 1889 Hardaway⁴⁹ speaks of xanthomatous diathesis in a case to which we shall refer later He also suggested that xanthomata is a "diathesis" and that its connection with hepatic disarrangement was entirely secondary, or in other words, that jaundice occurring during the course of the disease was a consequence of a deposition of xanthomatous tubercles in the "liver" This wise conception was not accepted and P Weber in 1903¹⁴⁸ as well as Futcher in 1905,⁴¹ reporting three cases from Osler's wards at Johns Hopkins, believed that chronic obstruction of the bile duct is the primary cause of the development of the xanthomata This opinion of Futcher is surprising because he describes "that on section of the liver the bile ducts stood out everywhere looking like sclerotic arteries The walls of the bile ducts are considerably hypertrophied containing elastic fibers and the lumina are lined with a mass of lymphoid and planum cells similar to those already described in the skin lesion" Posner, in 1909,⁹² describes a patient with bile duct obstruction who was operated upon but no obstruction found Xanthomata of the skin developed after the operation Hepatic cirrhosis and all kinds of xanthomatous changes in the organs were found at autopsy In 1900 Chvostek⁸² pointed out that "jaundice and xanthelasma" are the result of the same disease, namely they are due to a xanthomatous involvement of the liver which results in cirrhosis of this organ and to a xanthomatous involvement of the skin which is evident as xanthelasma"

S C Dyke, 1928,⁸⁴ in his paper on "Hypercholesteremic Splenomegaly" deals with the same disease—jaundice, xanthelasma planum and tuberosum, xanthomatous involvement of spleen and lymph nodes Buerger²⁵ describes a female 55 years of age with extensive xanthomata tuberosa and plana, jaundice and hepatic cirrhosis with the extreme total cholesterol value of 2575 mg per cent, 1444 mg per cent free and 1131 mg per cent esters A similar case with 1020 mg per cent total cholesterol is described by Weidman and Boston¹⁵² The autopsy findings in these cases showed biliary cirrhosis, xanthomata cells on the splenic and hepatic capsules, also on a scar of herpes zoster (like Hardaway's case) besides the extensive tuberosus xanthomata of the skin The most important feature of this paper is not the occasional finding of a polyp of questionable adenocarcinoma of the ampulla of Vater, but the photograph of the histological picture of the wall of the gall-bladder and the similarity of findings on the wall of the bile duct, both showing extensive xanthomatous changes and xanthomatous scar tissue It was recognized that the common bile duct was enlarged to the size of an

average thumb and the head of the pancreas was indurated, however, a cause for the dilatation in the form of biliary obstruction could not be demonstrated (Finding on laparotomy, immediately after which the patient died)

THE ETIOLOGY OF THE BILIARY CIRRHOSIS FOUND IN CASES OF JAUNDICE AND XANTHELASMA

Chvostek ³² showed for the first time that xanthoma cells and xanthomatous scar tissue are found in these cirrhotic livers

Our Case 14 (already reported by Schilling) exhibited the same findings of xanthoma cells scattered throughout the liver as the case of Chvostek and the case reported by Weidman and Freeman in 1928 ¹⁴⁹ It is evident that these nests of xanthomatous cells resulting in xanthomatosis of the liver undergo destruction sooner or later The result is the development of connective scar tissue and cirrhotic changes of the liver However, this process in the xanthomatous liver is not necessarily the main cause of the large cirrhotic liver of the biliary type of cirrhosis in all the described cases The main clinical symptom of this disease, "jaundice of years duration," would not be explained by a simple cirrhotic process of the biliary type

On the basis of an intensive study of the literature, and our experience, we believe that the xanthomatous changes on the walls of the larger bile ducts which are observed in almost all reported autopsies, and which give rise to the thickening as well as to the partial obstruction and dilatation of the bile ducts through the formation of xanthomatous scar tissue, are the cause of this peculiar biliary cirrhosis We know that chronic inflammation of the bile ducts leads very often to biliary cirrhosis Hence it seems reasonable that degenerative changes in the wall of the bile ducts due to xanthomata formation may also produce cirrhotic livers

The name "xanthomatous biliary cirrhosis" with xanthomatosis of the bile ducts may therefore be ascribed to this form of cirrhosis In naming this form of cirrhosis, first described by Addison and Gull in 1850, we would like to say that xanthomatous biliary cirrhosis is only one of the features of a systemic and usually hereditary disease which may involve different organs and produce different clinical pictures We shall see later that there are two distinct groups of organs which may be affected by xanthomatous changes resulting in peculiar symptom complexes However, xanthomatous changes may be observed isolated in one organ and, as in a few cases, involving almost every organ The former conception that the cause of the development of xanthomata is due to biliary cirrhosis and jaundice resulting from obstruction of the common bile duct by stones, inflammatory changes or tumor, does not meet with the facts and our clinical experience

Xanthomatous biliary cirrhosis due to xanthomatous involvement of the bile ducts shows in some instances nests of xanthomatous cells in small

areas of the liver tissue itself and in the spleen described as saffron yellow spots of pinhead size. These little xanthomata in the liver and spleen as well as in the capsule of the liver and spleen do not result in those extensive cirrhotic changes above described as "xanthomatous biliary cirrhosis" although they may be found in the same livers together with the xanthomatous involvement of the bile ducts.

On the other hand, the development of larger areas of xanthoma cells in the liver and especially in the spleen is described without jaundice and without cirrhosis but with enlargement of liver and spleen. In these cases of hepatosplenomegaly a high grade of lipemia was primarily observed. In 1931 Buerger and Grutz^{23, 24} describe such a patient, a boy of eleven years of age with a large liver and spleen, 9476 mg per cent of fat, 686 mg per cent total cholesterol, 310 mg per cent free and 376 mg per cent ester cholesterol. This boy was not jaundiced but there were xanthomata on the face, neck, arms and buttocks, also xanthomata in the mucosa of the mouth and in the larynx. Buerger and Grutz^{23, 24} report that the skin manifestations, in contrast to the findings of xanthomata tuberosa, did not show true xanthomatous tissue but only a few xanthoma cells. We would suggest that these nodules belong to the eruptive group of nodular papular xanthomata which come and disappear as described in our Cases 14, 15, 16 and as in severe lipemia in the diabetic Cases 21 and 22. Buerger and Grutz have not published up to now the further development of histological lesions in this unusual case but we agree with them that this case is different from the cases with jaundice and xanthelasma due to "xanthomatous biliary cirrhosis". The anatomical findings in liver and spleen of the "hepatosplenomegalic type without jaundice" may be similar to the findings of Lubarsch⁶⁸ in 1918, and Bross²² in 1920 in a case of xanthomatosis and diabetes mellitus with high grade lipemia where the enlarged liver and spleen as well as all lymph glands were filled with xanthoma cells. The case of Lubarsch-Bross forms a transition to a group to be presented later as "secondary xanthomatous diseases" with xanthoma cell formation in spleen and liver in diabetic lipemia. This condition was first described by Schultze¹²¹ in 1912 as "lipoid cell hyperplasia of the spleen".

Chemical Findings In our three cases, as in all cases of xanthomatous biliary cirrhosis in the literature where cholesterol determinations were made, there is high total cholesterol and in advanced cases of cirrhosis an inversed ratio of cholesterol cholesterol esters. High total cholesterol is in conformity with biliary stasis while inverse cholesterol cholesterol ester ratio indicates severe liver damage according to Thannhauser and Schaber and many others. The bilirubin of the serum is high and shows a direct and indirect reaction because in this kind of cirrhosis as in other biliary cirrhoses, bile stasis and liver damage is the underlying pathological condition.

Only Case 16, the lightest case of the three reported, was examined by our method to determine the monoamino- and diaminophosphatides. As

in the cases of cirrhosis the total phospholipids are high, the determination of lecithin (monoaminophosphatide) and sphingomyelin (diaminophosphatide) shows that the increase of total phospholipids in the serum is due only to an increase of monoaminophosphatide while sphingomyelin (diaminophosphatide) is normal or even diminished, a characteristic finding for all xanthomatous tissue, while in Niemann-Pick's disease the diaminophosphatide (sphingomyelin) is found excessively increased

Diagnostic Considerations The outstanding triad of symptoms in xanthomatous biliary cirrhosis is (1) enlarged liver and spleen with jaundice of years duration, (2) skin manifestations exhibiting tuberos and plain xanthomata of the elbows, knees, extensor surfaces of the extremities and buttocks, (3) hypercholesteremia with an inverse ratio of cholesterol cholesterol esters. The jaundice may be intermittent in character as in Case 16, but the liver and spleen remain enlarged and hypercholesteremia is always found, even during the time the patient does not show distinct jaundice. The skin xanthomata usually develop after the jaundice but in rare cases of tendon sheath xanthomata the xanthomatous biliary cirrhosis may develop in a later period of life. (Case 1 shows an inverse ratio of cholesterol cholesterol esters.) On the other hand, the xanthomata may develop very late as in Case 16. We are inclined to believe that the eruptive form of xanthomata (papulo-pustular form) may have been present in other cases reported in the literature, but the connection with the disease (that is with the hypercholesteremia) was not recognized. We would like to emphasize that this extremely itchy eruptive form which comes and goes is an aid to the early recognition of the disease.

CORRELATED FEATURES OF XANTHOMATOSIS OF THE NORMO-CHOLESTEREMIC TYPE

It is important to point out that certain features of xanthomatosis are found together. They are (1) xanthomata tuberosa and plana of the skin, (2) tendon xanthomata, (3) xanthomata formation on the endocardium and on the intima of blood vessels, (4) xanthomatous biliary cirrhosis and xanthomata formation in the liver and spleen. This group of xanthomata exhibit hypercholesteremia, high monoaminophosphatides, and high fat in the serum as well as in the tissues. The second group of xanthomatous diseases exhibit on the skin, if there is any skin involvement, most peculiar and for this group, characteristic universal lesions which are in localization, color and size, entirely different from xanthomata tuberosa and plana. This kind of xanthomata disseminata is associated with diabetes insipidus, involvement of the brain and nerve tissue, bones, lungs and lymph nodes. In contrast to the former group normal cholesterol or high normal cholesterol in the serum is the rule in this group.

I am very much indebted to Dr P A O'Leary, Dr H Montgomery and Dr A E Osterberg, Mayo Clinic, Rochester, Minnesota, for the permission to use Case 17 and Case 18 for publication in this paper.

XANTHOMATA DISSEMINATA

Case 17 S S, a man, aged 42 (1932) first seen in June 1927, had noticed increased thirst and polyuria in November 1925. He would drink about 20 glasses of water during the day and would wake up at night because he was thirsty. He could not remember any illness or other incident which might have brought on the condition. About the same time he noticed yellowish-brown elevated areas on the skin of the antecubital fossae. It seems probable that the appearance of these lesions antedated the onset of the diabetes insipidus but that they were not striking enough to attract the patient's attention for some time. Similar soft tumor-like nodules presently appeared in both axillae and on the sides of the neck, and smaller, paler plaques under the eyes. At his first visit, general examination was essentially negative except for the lesions on the skin in the areas mentioned. He was found to be passing not more than 2000 c c of urine daily and his oral fluid intake was recorded as not more than 2200 c c. The specific gravity of the urine varied from 1.006 to 1.012. Roentgenograms of the sella turcica were negative. The blood sugar was 0.10 per cent, the basal metabolic rate was normal, plus 3 per cent. A biopsy made from one of the nodules in the axilla revealed the typical picture of xanthoma.

The patient returned to the Mayo Clinic in January 1932, showing marked increase in the number and extent of xanthomatous lesions as compared with the status shown by photographs taken at the time of his previous visit. The progression had been so gradual, however, that he could not say whether they were still increasing or were stationary. About two years before this last visit, xanthomatous nodules had appeared around the anus and had been excised because of itching. They had recurred in an area of larger radius, and the itching associated with them formed his chief complaint. His thirst and polyuria were of less degree, he thought, than on his former visit. He had tried hypodermic injections of solution of pituitary in 1927 and had found that they controlled his thirst, but he had not experienced sufficient discomfort to continue the use of the drug.

Examination disclosed large areas of soft, confluent bronze-colored nodules in each axilla (figure 23). There were smaller areas in each antecubital fossa, where the nodules were pinkish-brown, some of these tumors were slightly pedunculated and as large as 2 by 1 by 1 cm. There were numerous smaller flat nodules on the neck, face, groins, and sides of the abdomen. Around the anus for a radius of from 6 to 7 cm the skin appeared smooth, gray and thick, perhaps owing in part to previous excision of nodules, at the periphery of this area were soft, sessile, pinkish tumors like those in the hollows of the elbows. A continuous ridge of nodules ran along the median raphe to the scrotum, where it ended in several nodular enlargements. Again, it was interesting to note that there were no lesions on the elbows, knees or surfaces subject to trauma. In the mucous membrane of the mouth there appeared five yellowish areas, one on the left margin of the tongue, one in each cheek, one in the left lower jaw and one in the uvula. There was no involvement of the posterior pharyngeal wall or scarring, as was present in Case 1. There were eight areas visible in the larynx and upper part of the trachea where the mucous membrane was similarly involved. As far as one could see down the trachea, the same condition was present. There was no scarring in the larynx or trachea and no embarrassment of respiration. On the upper part of each cornea covering the upper margin of the iris, was a yellow, slightly elevated mass resembling so closely some of the other nodules, particularly those in the mouth, that there seemed no reasonable doubt of their identical nature. Biopsy was made from a nodule on the arm and again revealed typical xanthoma, not differing essentially from the picture seen five years before in tissue from the same patient nor from that seen in sections made from the first patient (Case 1).

General examination was essentially negative except for the lesions described. The output of urine was between two and three liters daily, the specific gravity was

1010, urinalysis was negative. The concentration of hemoglobin was 10.8 gm (64 per cent), erythrocytes numbered 3.5 million per cu mm and leukocytes 11,700. Serologic tests for syphilis were negative. Roentgenograms of the thorax and sella turcica were negative. The eyegrounds were essentially normal. Analysis of the

FIG 23 Case 17 Xanthomata disseminata

chemical constituents of the blood gave these figures: cholesterol 167 mg, cholesterol esters 119 mg, total phospholipids 246 mg, fats as fatty acids 273 mg. One nodule was excised and the analysis of the dry tissue as follows: total cholesterol 4.55 mg per cent, cholesterol esters 3.66 mg per cent, fatty acids 3.64 per cent.

Treatment was begun as in the other case. Roentgen-ray exposures were made over the region of the sella turcica, both sides of the neck, and over the right arm. A diet low in calories and low in fat was tried. There was no improvement during the period that the patient remained under observation.

FIG 24 Case 18 Xanthomata disseminata in the axilla

Case 18 Mrs H A, married, aged 48 years, was examined at the Mayo Clinic in June 1936, because of polydipsia. In June 1935, she noticed small red and yellow lumps under the arms (figure 24) and in the groin which increased in spite of roentgen-ray treatment. In March 1936, many lesions developed on the eyelids (figure 25). Six months after the first onset of the cutaneous lesions (January 1936), she developed symptoms of diabetes insipidus, including marked polyuria and an

FIG 25 Case 18 Xanthomata disseminata of the eyelids

output of eight gallons of urine daily Diabetes insipidus was controlled fairly well by the use of pituitrin and amidopyrin Examination of the skin revealed red-brown nodules from the size of a pea to a pin, but none on the elbows, buttocks, knees and fingers There were also lesions in the mouth Blood chemical studies were as follows

| Date | 6/26/36 | 7/9/36 |
|--------------------------|--------------------|---------------------------|
| Total cholesterol | 214 mg per 100 c c | 235 mg per 100 c c plasma |
| Total fat as fatty acids | 302 | 250 |
| Total phospholipids | 305 | 269 |

The hemoglobin was 15.4 grams per 100 c c of blood, the erythrocytes numbered 4.9 million per cu mm and the leukocytes numbered 10,600 The differential count was as follows lymphocytes 31.0, monocytes 4.5, neutrophils 60.5, eosinophils 2.5, and basophils 1.5 per cent The flocculation test for syphilis was negative The urine showed specific gravity of 1.009 Roentgen-ray of the chest was negative Roentgen-ray of the skull, including the sella, showed a benign frontal hyperostosis

In February 1937, the patient returned The skin lesions had become much more numerous in the axilla and groin, and there was marked, diffuse, reddish infiltration of the face over the area usually involved by rosacea, made up entirely of milium xanthomata There was involvement under the eyes, over the axillae, lower portions of the breast, abdomen, labia, and inner surfaces of the thighs, and a few lesions were present in the cubital fossae,—all this in spite of the fact that the diabetes insipidus appeared to be quite well controlled (The liver was down about four fingers The spleen was not palpable) The patient was put on a low-cholesterol animal-fat-free diet The chemical analyses of the blood were as follows

| Date | 2/6/37 | 3/7/37 |
|---------------------|--------------------|---------------------------|
| Total phospholipids | 349 mg per 100 c c | 297 mg per 100 c c plasma |
| Total cholesterol | 273 | 231 |
| Fat as fatty acids | 514 | 405 |

At this time the erythrocytes were 4.6 million per cu mm and the leukocytes 8700 The urine showed a specific gravity of 1.007 There were xanthomata involving both cheeks, and the floor of the mouth There were some suspicious areas on the margins of the tongue, both arytenoid regions showed definite yellowish nodular areas

When the patient was examined May 10, 1937, she had been feeling well, and had been having very little trouble with thirst or polyuria She had been taking three amidopyrine tablets at night and three injections of pituitrin a week All the skin lesions were somewhat more extensive than in February The blood analyses on May 12, 1937, were as follows

| | |
|--------------------------|---------------------------|
| Total phospholipids | 260 mg per 100 c c plasma |
| Total cholesterol | 208 |
| Cholesterol esters | 134 |
| Free cholesterol | 74 |
| Total fat as fatty acids | 290 |

The bilirubin was 1.0 mg per cent—reaction indirect (The liver was no longer palpable)

Comment and Discussion It is remarkable that this form of xanthomata, until the paper by Polano⁸¹ (1936) and Montgomery⁷⁶ (1937) appeared, was confused with the other manifestations of xanthomata, although it differs in appearance, color, localization and size from the tuberous and flat form of skin xanthomata Under the title "xanthoma multiplex molluscum lipoides" Virchow,¹⁴⁵ who was the first to describe xanthoma

disseminata, adds to his paper a colored lithograph. On this lithograph the characteristics of this kind of xanthomata can be seen. The localization is on the hollow of the knees and elbows, not on the extensor surface, the color is not ochre or carrot-like but the color of a lemon at first and later dark brown like mahogany, sometimes with a metallic shiny surface. Virchow's patient was first seen by the famous ophthalmologist, von Graefe, because he had a xanthomatous nodule on the cornea similar to other cases of xanthoma disseminatum described in the literature by Weidman and Freeman,¹⁴⁹ and our Case 17. Stephen MacKenzie⁹⁸ in 1882 described, under the title, "Two Cases of Congenital Xanthelasma," two brothers and one sister with this peculiar kind of skin xanthomata (disseminata) in such an expressive manner that the difference between other xanthomata of the skin is seen at once. We quote his original description verbatim.

"Samuel H., aged 45. The eruption consists of very slightly raised, soft smooth patches of a lemon or chamois leather color, arranged somewhat in ridges or lines. The patches are of irregular shape and size, none much larger than a pea, and some not much larger than a pin-head. In places, as in the neck and abdomen they are so closely packed together as to appear confluent, but on stretching the skin the patches are separated by furrows. The larger patches are of deeper color and well defined, but the smallest are of a very faint lemon tint, fading into the healthy skin. The color is deeper in the exposed parts (as in the neck) than in covered parts. The affected skin is elastic and pliable and can be readily pinched between the fingers. There is not and never has been any itching of the skin and the patient has never experienced any inconvenience from it.

"*Distribution.* None on eyelids (most of the patients show affection of this part) nor on any part of the face or scalp. The neck is markedly affected, a band of the yellow plaques extending round it like a collar. From the neck the eruption extends over the scapulae and clavicles slightly. Both axillae are affected and the patches extend down over the integument covering the coracobrachialis and the biceps muscles. The bend of each elbow is slightly affected. There are a few faintly marked patches in the skin over the lower margins of each pectoral muscle. The lower lateral parts of the abdomen, the pubes, base of penis and scrotum are slightly and the groins are markedly affected. In the popliteal spaces are quite well marked patches.

"His brother, Jonathan H., aged 47, and his sister present a condition of the skin identical in character with that described on the neck, axillae, bend of elbows, groins and popliteal spaces. The sister is older than her brothers and remembers the eruption on the brothers' and on her own skin as babies. They have never caused any disturbance of their health. Neither has suffered from jaundice. Their paternal grandfather had a similar affection of the skin."

The familial occurrence of tendon xanthomata is widely known, the familial occurrence of xanthomata disseminata is only described in these cases of MacKenzie.

In studying the literature, we found xanthomata disseminata described but not differentiated from other xanthomatous manifestations, by Virchow¹⁴⁵ (1871), Poensgen⁹⁰ (1883), Eichhoff³⁵ (1884), Koebner⁶¹ (1888), Tschistakow¹⁴⁰ (1891), Anderson² (1882), E. Rhodes⁹⁸ (1906). In an outstanding but not commonly known paper Pusey and Johnstone⁹³ (1908) describe an 18 year old boy with a xanthomatous skin lesion "of

the diabetic type," associated with diabetes insipidus. The patient voided five liters of urine daily, specific gravity 1 002 to 1 006. The xanthomata are easily recognized by their description and localization as xanthomata disseminata. The skin was covered with an eruption varying from the size of a pin-head to a millet seed. The color was reddish in the small papules to a glistening yellow or bronze in the larger ones, which were confluent. The nodules were also seen on the mucosa of the mouth, epiglottis and larynx, cornea and sclera. The patient had spells of dizziness and fainting, during which he asked for water. Two years later tracheotomy was performed in order to relieve laryngeal stenosis caused by xanthomata. Later the spells of dizziness disappeared, but the diabetes insipidus persisted. Pusey deserves credit for having first described the clinical syndrome consisting of a peculiar form of skin xanthomata "intermediate form clinically between xanthoma diabeticorum and xanthoma multiplex" and diabetes insipidus. This peculiar form is, however, xanthoma disseminata and diabetes insipidus. He did not report in his first communication⁹³ (1908), as is erroneously quoted, xanthomata of the skull. W. H. Siemens¹²² describes, under the heading of xanthoma multiplex, what we believe to be xanthoma disseminata. Siemens, in collaboration with Rosenthal and Breunisch^{99b} first recognized that there are xanthomatous skin manifestations which are associated with normal cholesterol values in the blood in contrast to xanthomata tuberosa and plana. The difference in the appearance and the type of xanthomata was not emphasized by the various authors because the histological findings were the same as in xanthomata tuberosa and plana, and also because no single man observed a sufficient number of cases. Spillman and Watrin¹²⁶ (1921) describe in the French literature a boy who had xanthomata disseminata (according to the published photograph and to the description and the localization of the skin lesion) and diabetes insipidus. Neither bone changes nor exophthalmus were found. Turner, Davidson, and White¹⁴¹ (1925) indeed were the first who differentiated xanthomata disseminata from other xanthomatous eruptions. They reported and photographed a patient, who exhibited this characteristic kind of xanthomata. They describe the papules as 1 to 4 mm in diameter, varying in color from golden yellow to chocolate brown, distributed all over the body, around the neck, axillae, down the arms, involving both flexor and extensor aspects, eyes, abdomen, epiglottis, lateral aspects of the thighs and buttocks. The lesions of the mouth, pharynx, glottis, epiglottis, larynx and bronchi, as shown in the pictures, are unique in their extensiveness. The patient had an inspiratory and expiratory wheeze and the stenosis was so threatening that a tracheotomy had to be made as in Pusey's case.*

* Urbach (1928)¹⁴² describes a new manifestation of xanthomatosis with the name "lipoid proteinosis." The chief clinical manifestation is severe hoarseness. In the developed disease all cases present fairly hard, yellowish-white infiltrations of the inner surface of the lips, soft palate, fauces, uvula or under surface of the tongue. There are also some scar-like depressions. The larynx is similarly and severely involved. Two forms of the lesions are distinguished: (1) nodular and (2) hyperkeratotic lesions.

The clinical identity of these cases with those of Pusey and Johnstone, 1908,⁹³ Turner,

This patient, like Pusey's, had diabetes insipidus for three years, the onset of which coincided with that of the skin manifestations. Death occurred. The postmortem findings were very important because they showed for the first time that xanthomatous tissue may develop in the lung and pleura and produce a severe fibrosis of the lung. Roentgen-rays of the lungs were not taken, so that the very impressive picture of diffuse little nodules simulating miliary tuberculosis, but consisting of xanthomatous tissue, was missed during life. It is very important to note that the autopsy which showed xanthomatous plaques on the mucosa of the stomach did not show any involvement of the liver, of the vessels, or of the heart. The examination of the brain showed conglomerate xanthomata cells in the pituitary and the tuber cinereum. Unfortunately the bones were not examined. Pusey and Johnstone's⁹³ patient and that of Turner, Davidson and White¹⁴¹ were the first in whom the triad (1) xanthomata disseminata, (2) diabetes insipidus (brain involvement) and (3) xanthomatous disease of the pulmonary tissue was observed. Involvement of the bones has not been found, probably this was not looked for. In both cases there were neither xanthomata plana nor tendon sheath xanthomata, nor involvement of the blood vessels, bile ducts or liver. Blood sterols were normal in contrast to the reported cases in the other groups of xanthomata.

Recently Horsfall and Smith (1935)⁵³ reported under the title, "Lipoid Granulomatosis, Defects in the Bones, Exophthalmos and Diabetes Insipidus," a case with the complete clinical symptom complex of the group of xanthomatous diseases with normal cholesterol. The patient exhibited, according to the published photographs, typical xanthomata disseminata all over the body. The autopsy showed xanthomatous involvement of bones, lungs, dura of the brain, pituitary and spinal cord, lymph glands and spleen. Tendons, liver, bile ducts, and vessels were free, and xanthomata of the tuberous or flat form were not found. The cholesterol of the blood was normal.

K. Hoefer⁵² describes a seven year old boy with xanthomata disseminata. In this case xanthomata disseminata were combined with diabetes insipidus but this patient had in addition to these symptoms, exophthalmos and characteristic skull defects as described by Hand, Schueller and Christian.

Hermann and Nathan⁵⁰ describe a patient with xanthomata disseminata and normal cholesterol in the blood. The lungs and bones were not examined. Diabetes insipidus was not present.

In 1931 Finney³⁷ reported a case of typical xanthomata disseminata.

Davidson and White, 1925,¹⁴¹ and Finney, 1931,^{37, 38} is obvious. The photographs and colored pictures of the mouth and larynx published by Urbach are completely like the pictures of the case of Turner, Davidson and White. The skin manifestations of the "lipoid proteinosis" described by Urbach,¹⁴⁴ simultaneously with the lesions of mouth and larynx, are characterized by numerous pinhead-sized lesions grouped in mulberry-like, warty clusters. These lesions are, in view of size, appearance, localization and color (brown-violet sepia) identical with the lesions described first by Virchow 1871,¹⁴⁵ MacKenzie 1882,⁶⁸ and by different authors and are classified according to Polano,⁵¹ Montgomery and Osterberg⁷⁶ as "xanthomata disseminata."

situated on the eyelids, neck, axillae, groin and scrotum, some of the tumors were pedunculated (described as molluscum by Virchow) The mucous membranes of the mouth and larynx were involved The scarring of the larynx was "rhinoscleroma-like" The histological characteristics of these small xanthomata were the same as are seen in xanthomata plana and tuberosa xanthoma cells, chronic inflammatory and scar tissue This patient developed, one year after the onset of xanthomata disseminata, symptoms of diabetes insipidus with a daily urine output of six liters The cases of Finney, Montgomery and New,³⁸ Weidman and Schaffer,¹⁵¹ Montgomery and Osterberg,⁷⁶ show that diabetes insipidus and xanthomata disseminata may occur without bone and lung involvement The case of Weidman and Schaffer showed as a peculiar feature in the postmortem examination a xanthomatous involvement of the pons, this was also found in the case of Chiari^{29, 30} The involvement of the brain is not confined to the pituitary or the tuber cinereum as found in the patient presented by Weidman and Freeman¹⁴⁹ We shall discuss this later under a third group of patients

It is evident that we have to deal with two clinical symptom complexes of xanthomatous diseases These are to be distinguished by the kind of xanthomata exhibited on the skin, the organs involved and by the cholesterol figures found in the serum The one group consists of cases showing xanthomata tuberosa and plana, tendon sheath xanthomata, xanthomatous biliary cirrhosis with xanthomatosis of the bile ducts The other group shows disseminate xanthomata on the skin, xanthomatous involvement of the bones, skull, dura, brain (diabetes insipidus), scattered nests of xanthomata cells in the liver, spleen and lymph nodes without jaundice, but neither xanthomatosis of the bile ducts with xanthomatous biliary cirrhosis nor involvement of the tendons, intima of blood vessels or endocardium The kind of xanthomatous skin manifestations permits us to predict which visceral organs may be involved at the same time For this reason it is highly important to distinguish xanthomata disseminata from xanthomata tuberosa and plana as well as from the papulo-pustular eruptive form Even in the painstaking paper of Rowland^{100, 101, 102} we find his description of xanthoma disseminata mixed up with the description of the papulo-pustular eruptive form which may be present in hypercholesteremic conditions (diabetes mellitus and xanthomatous biliary cirrhosis)

Returning to Cases 17 and 18, it is evident that both belong to the second group of xanthomatous diseases (with normal cholesterol) Xanthomata disseminata and diabetes insipidus were the only features of this group observed in these cases According to our discussion of the literature, the xanthomatous manifestations in this group may be limited to these two symptoms, or they may involve other parts of the brain, the bones and the lungs

Histological findings In the photomicrograph of Case 17, larger groups of xanthoma cells are seen directly under the epidermis (figure 26) In

other xanthomata of the disseminata type the number of xanthoma cells is smaller, in older nodules xanthoma cells are not found at all

Chemical findings (Cases 17 and 18) The cholesterol content of the blood in these patients was a high normal, in fact in Case 18 the first de-

FIG 26 Case 17 Histological picture of xanthomata disseminata

termination was slightly increased but not as high as in the group of cases with xanthomata tuberosa and plana. In these cases only the total phospholipids were examined and not differentiated as monoaminophosphatides and diaminophosphatides. The low value of total phospholipids in Case 18 demonstrates also that this case belongs to the group of the normocholesteremic type. An organ analysis was not done because of the small size of the individual lesions. The significance of a normal content of cholesterol and phospholipids in the blood for the mechanism of the disease will be discussed later. At this point, however, we should like to emphasize that we do not believe that the two groups are different diseases although they are clinically different in regard to the organs involved and chemically different in regard to the cholesterol-phospholipid content of the serum. The two groups represent different features depending on the organs involved, but the anatomical changes characterized by xanthoma cell formation are the same.

OSSEOUS XANTHOMATA

Case 19 C S, a 51-year-old Italian carpenter, noticed multiple excrescences developing in the region of his right ear and at the external canthus of his right eye when he was 35 years old. There was sero-hemorrhagic discharge from the right and several years later from the left ear as well. At the age of 41 numerous soft

FIG 27 Case 19 Deformity of the skull and of the orbits

tender masses appeared on his head and drained sero-hemorrhagic fluid. Some of the older lesions ceased draining subsequently but other new ones appeared and drained. At about that time bilateral exophthalmos appeared and he began to suffer from polydipsia and polyuria (figures 27, 28). He was told at a hospital that his skull was paper-thin and that he had but three or four months more to live. He continued working, however, until at the age of 47 he fell down stairs and fractured his left femur and right humerus. In the Beth Israel Hospital, Boston, a plaster cast was applied and he was treated with irradiation by roentgen-rays. His fractures healed, the draining of the sinuses of his skull ceased and he was up and about, feeling well. His diabetes insipidus responded to a preparation of pitressin in oil. Fasting blood sugars were frequently elevated and a glucose tolerance test showed a diabetic type of curve. At no time was sugar present in his urine. His blood cholesterol values varied from 145 mg per cent to 235 mg per cent during his stay in the Beth Israel Hospital.

During the following years he developed a gradual unrecognized distention of the urinary bladder and became totally deaf. He knew of no member of his family with a similar condition or other manifestation of xanthomatosis.

We are indebted to Dr J D Adams for referring this patient to us and to Dr M J Schlesinger for permission to publish the histological slides.

On admission to the Diagnostic Hospital of the New England Medical Center January 9, 1937, he was slightly obese, not icteric, very thirsty and urinating at frequent intervals. His skull was strikingly deformed, showing a number of bulging areas and depressions which involved also the facial part of the head. The depressions were hole-like and funnel shaped, the surrounding bone was not thin, flexible or tender. None of these areas showed secretion. There was marked exophthalmos of both eyes. In the skin of both upper and lower lids, were several soft swellings, lighter and flatter than the xanthelasma (figure 29). His pupils were round, reacting to light and on accommodation, his fundi showed no abnormalities. Both ear canals

FIG 28 Case 19 Exophthalmos

were filled with soft, yellowish material which revealed no cholesterol crystals on microscopic examination. There was total nerve deafness. The mucous membranes of the mouth and throat showed no abnormalities. Heart and lungs were essentially normal. Blood pressure 160 systolic and 98 diastolic. In the lower abdomen the distended bladder extended above the umbilicus. After removal of 1000 c c of urine the bladder was still palpable above the symphysis. Liver and spleen were not palpable and not definitely enlarged on percussion. The right humerus and left femur were markedly deformed and shortened with limited motion in the right elbow and left knee joint. The skin of both hands was dry and hyperkeratotic. This condition was more marked over both lower legs where there were large, grayish-brown scales and onychogryphosis of the nails of both big toes. The thoracic spine was kyphotic and the patient's gait awkward, stiff and limping. He could walk only with the aid of a cane. No definite abnormalities of the central nervous system were demonstrated except the bilateral deafness, an occasional coarse tremor of the head and the *ischuria paradoxa*.

The volume of the urine varied from 4000 to 9600 c c daily. It contained from 36 to 75 grams of sugar daily. On a diet of carbohydrate 150 grams protein 80 grams, and fat 100 grams, with 20 units of insulin twice daily, he remained sugar-

free Under insulin treatment the urine volume diminished to between 1200 and 2500 c c daily

Fasting blood sugar varied from 224 to 252 mg per cent The glucose tolerance curve was diabetic in type

Roentgen-rays of the skull (figure 30) showed what has been described as a geographical map, the tables of the skull being irregularly eroded in areas varying from pin-point size to large irregular-shaped defects. The sella turca was not particularly enlarged. There was extreme increase in density at the base of the skull involving both mastoids, sphenoids and roofs of the orbits (figures 31, 32).

Roentgen-rays of the femora showed a few areas of decreased density in the head of the right femur, a large callous mass in the upper half of the left femur. There was a definite erosive lesion at the outer circumference of the right ilium, just above the head of the femur.

Chemical findings of Case 19 The cholesterol figures in this case show normal total cholesterol and normal cholesterol esters ratio in conformity with the figures reported in similar cases in the literature. In contrast to the normal cholesterol the total phospholipids are high. The individual determination of mono- and diaminophosphatides reveals that the increase of phospholipids is due to an increase of lecithin-cephalin fraction. The diaminophosphatides are low so that the ratio of diamino monoaminophosphatides which usually varies from 1.05 to 1.1 reads 1.66. We found a similar abnormal ratio in another one of this group but we would not like to stress this finding at this time because the significance of low values of diaminophosphatides which led to this abnormal ratio is not known.

FIG 31 Case 19 Roentgen-ray of the humerus, showing spontaneous fracture and xanthomatous cysts

FIG 32 Case 19 Roentgen-ray of the femur, showing spontaneous fractures and xanthomatous cysts

Histological findings of Case 19 The xanthomatous tissues of the excised nodules of the dura contained more granulomatous tissue than do tuberous xanthomata of the skin. There were scattered xanthoma cells and conglomerate nests of cells in granulomatous tissue as shown in the photographs (figures 33, 34). Giant cells and

FIG 33 Case 19 Histological picture showing the xanthoma cells of a xanthomatous nodule of the dura

exudate cells were observed in the granulomatous nodules. There was no outstanding difference in the histological findings between the xanthomatous nodule of the dura and other xanthomatous tissue.

Comment and Discussion There is no question but that this case belongs to the group of cases which were first described by Hand (1893),⁴⁷ Kay (1905),⁵⁸ Dietrich (1913),³³ Schueller (1915),¹¹⁹ Christian (1919)³¹ under different headings of bone diseases associated with diabetes insipidus. These authors did not recognize that this group of patients belongs to the group of xanthomatous diseases although Dietrich³³ called his case "fibro-

xanthoma" Rowland (1928)¹⁰¹ deserves the credit of having proved conclusively (after reporting two of his own cases and discussing the others) that the defects in the membranous bones, the diabetes insipidus and the exophthalmos were due to xanthomatous changes in the bone marrow, to xanthomatous nodules of the dura and periosteum of the skull and orbit and to xanthomatous changes in the brain. The autopsy on one of Row-

FIG 34 Case 19 A nest of xanthoma cells in a xanthomatous nodule of the dura

land's patients revealed these facts and showed that in addition to the bones, dura and brain, xanthomatous changes occurred in the lungs, pleura, lymph nodes and spleen.

We have reported above two cases (17 and 18) of xanthomata disseminata associated with diabetes insipidus. Similar cases in the literature show conclusively that xanthomata disseminata of the skin, xanthomatous changes in the brain (diabetes insipidus), xanthomatosis of the lungs,

lymph glands, spleen and bones belong to one group of xanthomatous disease (To this group belong the cases of Pusey and Johnstone,⁹³ Spillman and Watrin,¹²⁶ Turner, Davidson and White,¹⁴¹ Horsfall and Smith,⁵³ and K. Hoefer⁵²)

The question arises as to whether the Hand-Schueller-Christian symptom complex is a special kind of xanthomatous disease or whether it should be included in the group of xanthomatous diseases characterized above as involving the skin (by xanthoma disseminata), the bones, the brain and dura, lungs, lymph nodes, and the spleen. It would appear that Hand-Schueller-Christian's disease clinically belongs to this group and is not an independent clinical entity. To justify this assumption we offer the following facts: (1) We find xanthomata disseminata occurring alone, with diabetes insipidus, with the Hand-Schueller-Christian syndrome, and with bone lesions (Hand,⁴⁷ Horsfall and Smith,⁵³ Pusey and Johnstone⁹³), (2) xanthomata of the lungs occur with xanthomata disseminata, with bone lesions, with diabetes insipidus, and with Hand-Schueller-Christian syndrome (Turner, Davidson and White,¹⁴¹ Rowland^{101, 102}), (3) xanthomata disseminata alone or combined with diabetes insipidus, as well as the Hand-Schueller-Christian syndrome have a normal or high normal serum cholesterol.

The features of the Hand-Schueller-Christian syndrome which seem to separate it from the group are the lesions of the membranous bones and exophthalmos. The membranous bone lesions may occur, however, as a part of general osseous xanthoma without diabetes insipidus and without exophthalmos. Two cases of Fraser,⁴⁰ and our Case 20 (see below) illustrate this. The bone lesions as well as the exophthalmos have been shown by Rowland¹⁰¹ and others, to be due to granuloma-like deposits of xanthomatous tissue formed by the same components as other xanthomata, namely, xanthoma cells, giant cells, exudate cells and granulomatous tissue. Exophthalmos and skull lesions are therefore the result of the same underlying anatomical substrate, as are all xanthomatous diseases. Rowland (1928)¹⁰¹ collected 14 cases, Sossman (1932)¹²⁵ 45 cases (6 of his own) and Horsfall and Smith,⁵³ 50 cases of xanthomatous bone disease of the Hand-Schueller-Christian type. The number of cases would be decidedly higher if to these cases were added the patients with bone lesions and xanthomata disseminata with and without diabetes insipidus which belong to the same group.

The clinical features of our Case 19 do not differ essentially from the usual juvenile cases of the disease. The onset of the disease in this case at the age of 35 is, however, quite unusual, though there are already three cases of Hand-Schueller-Christian syndrome reported in patients over 40 years of age (Sossman,¹²⁵ Chester²⁸). The usual age of onset in these patients is the first decade of life. The draining ear of our patient was due to xanthomatous involvement of the mastoid bone as is also observed in

juvenile cases The enlargement of the bladder is probably due to failure of neurogenic control The patient exhibited the symptoms of *ischuria paradoxa* I had the opportunity to see another case of Hand-Schueller-Christian's syndrome with Dr Blackfan of the Children's Hospital in Boston This case, which is published by Dr Sossman¹⁻⁵ as Case 3 in his series has also at present a distended bladder and symptoms of *ischuria paradoxa* Disturbances of the bladder regulation are not reported in cases of diabetes insipidus It seems likely that xanthomatous changes in the spinal cord may be present

Case 20 S S, a four-year-old female child No family history of bone diseases She began to limp and roentgen-rays were taken by her physician which revealed multiple bone lesions of the hyperparathyroid type The child was sent to Dr Fuller Albright at the Massachusetts General Hospital to whom I am indebted for the privilege of seeing the child with him and for permission to use the case for this paper Her appearance was that of a normal four year old child There were no signs of xanthomatosis of the skin, skull formation was normal, no exophthalmos, no diabetes insipidus

Tissue (dried) Cholesterol content 2.07 mg %

In contrast to the fact that the child was normal in appearance is the roentgen-ray report of her bones "April 9, 1936 The skull, pelvis, femora, tibiae, left scapula, left ulna, right radius, both humeri, the right ninth and tenth and left sixth ribs show smooth sharply defined punched out areas of bone destruction (figures 35, 36) The most extensive changes are seen in the upper ends of the left femur and in the wings of the ilia The head of the left femur is partially destroyed and the shaft of the left femur in the region of the trochanter and neck show multiple vacuolated areas of diminished density with smooth sharp dense margins The lower end of the left femur and the upper end of the tibiae show irregular calcium deposits in lesions which may have been areas of destruction There is a lesion in the left humerus at the junction of the middle and lower third which is quite unlike all the other lesions described It is characterized by moth-eaten bone destruction and extensive periosteal proliferation along about 3 inches of the shaft on the lateral surface No fracture is seen at this point and the soft tissues are normal The bones show a slight degree of osteoporosis and their density is within normal limits except in the region of the lesions described

"Comparing these films with those taken on May 28, 1934 shows definite increase in the number and size of the lesions There has been apparent complete healing in a lesion at the upper end of the left humerus since 1934 It is probable that the lesions in the lower ends of the femora and tibiae are likewise healed but no previous films are available for comparison"

Tissue was obtained by biopsy from the bone marrow of the scapula The amount

of cholesterol in this material is given above. The histological findings (figure 37) as reported by Dr. Granville Bennet of the Harvard Medical School are as follows: "The tissue is very vascular, being traversed by numerous thin-walled capillaries. In most areas there is little supporting tissue between capillaries. However, in a few areas there are larger amounts of connective tissue that indicate slight fibrosis of the bone marrow. The cytological picture of the tissue is greatly varied. Large col-

FIG 35 Case 20 Roentgen-ray of the skull Cystic xanthomatous bone lesions

lections of bone marrow cells are observed in some areas. In other areas the hematopoietic cells are scattered in between good-sized collections of large mononuclear cells which appear definitely abnormal. These cells vary markedly in size and shape. The majority are oval or round. The cytoplasm is usually well stained with eosin dye. In many of the cells, however, the cytoplasm is finely vacuolated or contains brownish pigment, or in some instances it contains both pigment and finely divided vacuoles. The nuclei of the majority of these cells are oval or kidney shaped. Certain areas show marked accumulations of these cells. However, in the majority of fields such cells are scattered in small groups, through the marrow tissue.

"Frozen section stained with Scharlach R show large accumulations of lipid in finely divided globules. This material stains bright red.

"Sections stained with potassium ferrocyanide and dilute HCl show no recog-

nizable iron in the cells that contained brownish pigment in hematoxylin and eosin stained preparations"

Study of this material suggests that the skeletal defects were caused by accumulations of lipid-containing cells and that the lesions represent one form of skeletal xanthomatosis

Fig 36 Case 20 Roentgen-ray of pelvis Xanthomatous cystic bone lesions

Comment and Discussion Case 20 shows xanthomatous involvement of the osseous apparatus only, skull, scapula, ribs, pelvis and extremities. There was no diabetes insipidus and no exophthalmos. The skin was always normal, with no evidence of xanthomata disseminata. The differential diagnosis from multiple myeloma was, therefore, difficult and was only possible by biopsy, which revealed typical foam cells in the bone marrow of the scapula. The chemical examination of the serum showed normal values of cholesterol, as well as phospholipids. The chemical determination of cholesterol in the biopsy tissue from the bone marrow exhibited increased figures for total cholesterol (2 mg per cent) but these were not as high as those found in other tissues by Chiari and Epstein³⁰ (18.58 mg per cent), Kleinmann⁶⁰ (15.8 mg per cent) and Letterer⁶³ (9.6 mg per cent), these were percentages of the dried tissue. In Case 1, 9 mg per cent were found and in Case 9, 13.1 mg per cent. Our Case 20 was unusual insofar as the bones only were involved by xanthomatous changes, but two similar cases have been reported by Fraser.¹⁰

The case of Letterer,⁶³ which also exhibited bone changes without diabetes insipidus and without skin manifestations, showed as an outstanding

feature a xanthomatous involvement of the lymph nodes as in Hodgkin's disease. There were no figures of the cholesterol content of the serum because the patient was diagnosed during life as having Hodgkin's disease,

FIG 37 Case 20 Histological picture of a xanthomatous nodule of the bone marrow

although the serum was grossly reported as lipemic. The granulomatous features were so prominent that Letterer speaks of xanthomatous (in the original, xanthoesei) lymphogranulomatosis. Merrill (1920)⁷⁵ described a case of multiple bone lesions with xanthomata tuberosa and plana and

tendon xanthomata The cholesterol content of the blood is reported as very high (figure not given) The published photographs showed the bone cysts to be of very small size and the evidence that they were true xanthomatous bone cysts not convincing There is in the literature not one undoubted case reported of tendon xanthomata and xanthomata plana associated with xanthomata of the bones, whereas xanthomata disseminata are usually seen in such patients affected with osseous xanthomata Further, normal serum cholesterol values are reported in such cases Another doubtful case of xanthomatosis involving only the bones is reported by Snapper and Parisel¹²⁴ Their patient, a girl, showed brown nevi on the skin but not xanthomata The bone biopsy showed changes similar to those in osteitis fibrosa cystica Another biopsy was reported to have shown foam cells According to the paper of Allbright, Butler, Hampton and Smith,^{1a} the case of Snapper and Parisel¹²⁴ does not belong to true osseous xanthomata Two cases reported by Chester²⁸ as lipid-granulomatosis, one a woman of 44, the other, a man of 69, were found to have extensive xanthomata of the bones In neither of these cases was diabetes insipidus or exophthalmos observed during life Xanthomatous involvement of the lungs and pleura was found at autopsy

Our case 20 belongs to those unusual cases of xanthomata where the granulomatous features of the tissues were predominant, and xanthoma cells scarce The low cholesterol values in the analyzed tissue are the chemical expression of this fact However, there is no doubt that, according to the biopsy, Case 20 exhibited xanthomatous involvement of the bones

The attempt has been made in the description of these 20 cases and in the discussion of the literature to distinguish between two clinical groups of primary xanthomatous diseases The characteristic features in the one group are (1) xanthomata plana and tuberosa, (2) tendon and tendon sheath xanthomata, (3) xanthomatous involvement of the wall of the bile duct with xanthomatous biliary cirrhosis, (4) xanthomatosis of the wall of the blood vessels and endocardium, (5) high values of total cholesterol in the serum, increased fraction of lecithin and cephalin, increased fat, (6) eruptive form of skin xanthomata, (7) xanthoma cell nests in the spleen, lymph nodes and liver

The features of the other group are (1) xanthomata disseminata of the skin, mouth and larynx, (2) xanthomatous involvement of the pituitary and tuber cinereum with the features of diabetes insipidus, xanthomata in the brain and medulla, (3) xanthomatous nodules on the dura and orbit, (4) osseous xanthomata, (5) xanthomatous involvement of the lung and pleura with consequent fibrosis, (6) normal or high normal total cholesterol in the serum, normal lecithin and cephalin fraction, normal fat, (7) scattered nests of xanthoma cells in the spleen, lymph nodes and liver (also present in the first group)

The two groups differ in the organs involved as well as in the lipid chem-

istry of the serum The main histological findings in all types of lesions are the same, namely xanthoma cells, granulomatous scar tissue with giant cells and exudate cells, varying according to the age of the lesion We would like clinically to distinguish these two groups of xanthomatous diseases as "hypercholesteremic" and "normocholesteremic" types We must, however, be aware that the underlying disease, that is "essential xanthomatosis," is the same in both groups

Only three cases, where the organs involved by the xanthomatous process comprise both groups in one patient, could be found in the literature (1) Hardaway (1889)⁴⁹, (2) Weidman and Freeman (1924),¹⁴⁹ Griffith (1922)⁴⁶ (case is identical with Weidman and Freeman), (3) Weidman and Stokes (1937),¹⁵⁰ Gitting (1929)^{45a} (case is identical with Weidman and Stokes) Hardaway's patient exhibited xanthomata disseminata (face, neck, axillae, trunk, extremities, as well as mucous membranes of the mouth and larynx), osseous xanthomata of the long bones, xanthomatous lesions in herpes zoster as well as hepatic cirrhosis with jaundice and xanthomata of the tendons Hardaway speaks of a xanthomatous diathesis He suggested, like Quinquaud, 1879,^{95a} who used the expression "diathèse xanthomatique," that xanthoma formation is a "diathetic affection" and that its connection with hepatic disease was entirely secondary or, in other words, that jaundice occurring during the course of the disease was a consequence of "a deposition of xanthomatous tubercles in the liver"

Weidman and Freeman's patient¹⁴⁹ is the most completely studied case, illustrating the combined group, excellent histological photographs of all organs involved are published This nine year old boy showed, as did Hardaway's patient, xanthomata disseminata and xanthomata plana, "hundreds of little nodules on mouth, neck, axillae, elbows, knees, also in the lines of the palms The margins of all four lids have long flat lesions There were several nodules on the side of the head, the underlying bones were depressed and roentgenograms showed small bony defects of the frontal and parietal regions" The boy was jaundiced, polyuric (diabetes insipidus) and had an enlarged liver Total cholesterol 397 mg per cent The post mortem revealed xanthomatous involvement of the skin, brain, pituitary and tuber cinereum, diffuse xanthomatosis of the lung, xanthomatous biliary cirrhosis, xanthomatous changes in the lymph nodes, xanthomata of dura and skull

The third case of the combined type, a girl 6 years of age, reported by Weidman and Stokes,¹⁵⁰ showed tuberous xanthomata in operative scars, and in our opinion the eruptive form of xanthomata, associated with a very high blood cholesterol (1039 mg per cent) (Gitting^{45a} reported in 1928 the same case with a blood cholesterol of 120 mg per cent) There was also diabetes insipidus but no exophthalmos The roentgenogram did not show skull involvement There were xanthomata on the roots of the teeth, jaundice and a large liver No autopsy

CLASSIFICATION OF ESSENTIAL XANTHOMATOSIS

At the present time, primary xanthomatosis is classified by Rowland¹⁰² as embracing skin and mucous membrane, tendon sheath and visceral varieties, also as a separate entity—Schueller-Christian's disease. Buerger²⁵ classifies the disease into three groups (1) essentially osseous, (2) essentially cutaneous and (3) essentially visceral localization. On study of our 20 cases and the reported cases in the literature, it seems to us that the clinical pictures and the anatomical facts do not warrant such a division. The clinical pictures show conclusively that the xanthomatous manifestations of the skin are different in appearance and significance. We tried to point out that certain well characterized forms of xanthomata of the skin are correlated with different xanthomatous manifestations of various organs. Two different groups of primary xanthomatosis are distinguishable without difficulty. Both groups differ, not only in the visceral organs affected and the skin manifestations, but also in chemical findings in the serum (hypercholesteremia on the one hand and normocholesteremia on the other). The description of three cases in the literature, where the features of both groups of xanthomata are found in one patient (combined group) reveals conclusively that primary xanthomatosis is a systemic disease. Primary xanthomatosis (metaplastic reticular cholesterosis) may occur isolated in one organ or combined in two different groups of organs or generalized in all organs which contain reticulum cells and histiocytes.

THERAPY OF ESSENTIAL XANTHOMATOSIS

The two groups of xanthomatous diseases respond differently to therapeutic procedures. The xanthomatous diseases of the hypercholesteremic type show a marked decrease of the hypercholesteremia, as well as a decrease of the other blood lipids after a period of cholesterol and fat-poor diet. Such diets have been described by me¹³⁷. They contain only vegetable fats because plant sterols are not absorbed (Schonheimer¹¹⁵). The xanthomatous diseases of the normocholesteremic type do not respond to diet treatment at all. We applied in both groups, in addition to the diet treatment, small doses of Thyroidin, one gram daily, with good effect in the hypercholesteremic group, while in the normocholesteremic group an influence on the cholesterol content of the serum was not evident.

The osseous xanthomata and the dura xanthomata of the cases of the normocholesteremic type respond to roentgen-ray therapy very satisfactorily according to Sossman and other authors. Whether the other organs (skin, lungs, brain) belonging to the symptom complex of the normocholesteremic type react to roentgen-ray favorably is not known. The skin xanthomata belonging to the group of the hypercholesteremic type, however, as well as the tendon xanthomata, are not influenced at all by roentgen-ray.

SECONDARY XANTHOMATOSIS

The two cases to be reported here were observed at the Deaconess Hospital by Dr Elliott P Joslin and his associates, to whom I am indebted for the privilege of publishing the records

Case 21 The patient was in acidosis when first seen by Dr Joslin, January 15, 1934 Glycosuria 7.4 per cent, blood sugar 250 mg per cent, insulin 56 units daily He showed lipemia retinalis and an eruption characterized by nodular pustules, surrounded by narrow pink zones

The localization of these nodular-pustular eruptions which come and go is usually all over the body except for the scalp The nodular pustules vary in size from a small pinhead to a grain of wheat There are a few larger lesions formed by the confluence of adjacent lesions The lesions for the most part consist of a light yellow tip upon an inflammatory reddish base, which may change color in due course to violet and brown Except on close inspection, they would be taken for true pustules Indeed, physicians and patients have opened them in an effort to remove the yellow material seemingly present on the tip and have been puzzled to get only blood and a little white serum It is noticeable that the lesions do not always have a yellow tip, therefore the etiology is usually not recognized Some of the lesions are excoriated by scratching, due to itching These lesions come and go In this case, they had disappeared within five months after insulin and diet treatment was instituted which had effected also a complete disappearance of the lipemia

Case 22 Patient 32 years of age, seen September 18, 1934 Weight 132 pounds Insulin 52 units Feels fine Diabetes discovered in December 1925 The diagnostic remark was "a mild diabetes, but not very cooperative" Eight years later the patient was seen again At this time, April 29, 1933, hard xanthomatous lumps were found in the right heel Plasma cholesterol was 644 mg per cent, blood sugar 120 mg per cent On August 17, 1934, simultaneously with lipemia and definite lipemia retinalis, an eruption appeared of many small yellowish papules scattered diffusely on arms, chest and lower back Glycosuria 3.3 per cent Blood sugar 220 milligrams Plasma cholesterol 768 milligrams

Comment and Discussion We owe the first description of this kind of eruptive xanthomata to Addison and Gull,¹ who described its occurrence in a diabetic in the historical paper already mentioned as giving the first description of xanthomata plana and tuberosa with biliary cirrhosis Their description follows

"The eruption somewhat suddenly appeared on the arms In the course of

ten days, it had extended over the arms, legs and trunk, both anteriorly and posteriorly, also over the face and into the hair, it consisted of scattered tubercles of various sizes, some being as large as a small pea together with shining, colorless papules. They were most numerous on the outside and back of the forearm, and especially about the elbows and knees, where they were confluent. Along the inner side of the arms and thighs, they were more sparingly present, and entirely absent from the flexures of the larger joints. Besides the compound character produced by the confluence of two or three tubercles, which appeared to be such, as shown by the prominent whitish nodules upon them, some looked as if they were beginning to suppurate, and many were not unlike the ordinary molluscum, but when incised with a lancet, they were found to consist of firm tissue, which on pressure gave out no fluid save blood.

"They were of a yellowish color, mottled with a deepish rose tint, and with small capillary veins here and there ramifying over them. They were accompanied with a moderate degree of irritation, hence the apices of many were rubbed and inflamed."

This eruptive form so excellently described almost ninety years ago was characterized as "xanthoma diabeticorum." Many authors designate as xanthoma diabeticorum not only the eruptive form, which comes and disappears simultaneously with the lipemia, but also xanthomata tuberosa and plana, which are persistent. This confusion results from the fact that xanthomata tuberosa and plana are observed simultaneously with a mild diabetes as described in our Case 22 and in Case 4. In these cases, xanthomata tuberosa are features of primary xanthomatosis, when at the same time as the skin, visceral organs are involved. Xanthomata diabeticorum on the contrary are not the cause but the sequel of a complication in diabetes. This complication is lipemia. Xanthomatosis diabeticorum, that is the eruptive form of xanthomata, occurs not only in high lipemia during severe diabetes, but also in primary xanthomatosis, if high lipemia is present. This fact is evident in the three cases with xanthomatous biliary cirrhosis without diabetes but with lipemia. The eruptive form of xanthomata described and pictured in these cases of primary xanthomata is identical in appearance as well as in its transitory character with the eruptive form of xanthomata occurring in severe diabetes without primary xanthomatosis, and known as xanthomata diabeticorum. In the above described Case 22, tuberos xanthomata and mild diabetes were present for many years until rather suddenly lipemia was noted as lipemia retinalis and the eruptive form of xanthomata occurred. The eruptive form of xanthomata and lipemia disappeared, but the xanthomata tuberosa and hypercholesteremia persisted. A similar case is described by Major^{71, 72} (1924), who pointed out that xanthomata diabeticorum is connected with lipemia and not primarily with diabetes.

We should like to emphasize that the eruptive form of xanthomata (xanthoma diabeticorum) is etiologically entirely different from all xanthomata due to primary xanthomatosis. The latter is a systemic disease. The eruptive form is a symptom of lipemia and may occur in diabetic

lipemia as well as in lipemia during xanthomatous disease as in xanthomatous biliary disease

We have already pictured the histological findings of the eruptive form of xanthomata (figure 22) In the photographed specimen xanthomata cells are not found But there are reports in the literature that besides the signs of inflammation, there are found some rare xanthoma cells R H Major points out this difference from true xanthomata He described his findings as follows

"A section from one of the excised nodules showed marked evidence of inflammation The corium was thickened, extensive keratinization had taken place, there were areas of small, round-cell infiltration, marked fibrotic changes present and the characteristic large xanthoma cells were recognized with difficulty"

The xanthomatous lesions described by Urbach¹⁴² as extracellular cholesterosis should now be discussed "The essential lesions are lentil-sized, hard translucent nodules, sometimes with a central blister After one or two days they become blue-violet, generally with a yellow center and later still reddish-brown Sometimes at the beginning the eruptions resembled erythema multiforme Some of the lesions disappeared after a few days and even nodes of long duration regressed considerably under roentgen-ray" The histological findings in Urbach's nodules of extracellular cholesterosis exhibit vascularity of the cutis with damage to the vascular endothelium and infiltration with round and spindle cells In none of the preparations was there the slightest indication of foam-cell formation The lipid was entirely extracellular, first around the vessels and later in the whole cutis The lipid was found by staining and chemical analysis of the lesion, which revealed a cholesterol to cholesterol ester ratio of 3 : 1 in contrast with true xanthomata tissue of 1 : 1.5 These figures are impressive indeed But if we really considered the material chemically analyzed in the case of the eruptive xanthomata (extracellular cholesterosis), the value of those figures is doubtful because the quantity of material must have been minimal and the quality of material is varying and uncontrollable in view of the minimal amount of pathological tissue and the amount of healthy tissue chemically examined in the same specimen Chemical analysis of pathological tissue is of value only if a large amount of characteristic tissue like true xanthomata can be analyzed Be the value of the chemical findings what it may, the clinical description of the lesions of "extracellular cholesterosis" by Urbach is in conformity entirely with the clinical appearance of eruptive xanthomata first described as xanthomata diabeticorum by Addison and Gull, and many subsequent authors

The differential diagnosis of the eruptive form of xanthomata from xanthomata disseminata which are true xanthomata, that is, the skin manifestations of a systemic disease which simultaneously involves a group of organs, should not be difficult The eruptive form is scattered, never in ridges, never mulberry-like or in warty clusters, nor are they pedunculated

The lesions are isolated or in small groups. The color of the lesions in xanthomata disseminata is lemon yellow or in older lesions a deep reddish brown, mahogany-like. They grow in ridges and clusters with localization around the neck, axillae, and in the bend of elbows and knees.

Sometimes it may be difficult at first to differentiate the eruptions from erythema multiforme, but the colorations and vascularization of the nodule is characteristic after a few days so that the eruptive form of xanthomata cannot be easily mistaken. The blood findings of high cholesterol (the ratio of cholesterol to cholesterol esters may be normal in diabetes, and reversed in xanthomatous biliary cirrhosis), high fats and lipemia confirm conclusively the diagnosis already made clinically.

That the eruptive forms of xanthomata and xanthomata diabeticorum are identical should be emphasized. Hyperlipemia and hypercholesteremia result in this kind of skin eruption, which we consider as secondary to the high grade of lipemia occurring in the course of severe diabetes mellitus or in the course of xanthomatous biliary cirrhosis. Therefore, the skin manifestations of primary xanthomatosis must be differentiated from the eruptive form of xanthomata, the so-called xanthomata diabeticorum, which are classed in the group of secondary xanthomata. Xanthomata tuberosa, on the other hand, are independent features of primary xanthomatosis and occur at times with diabetes mellitus. Their presence in diabetes is an indication that the systemic primary xanthomatous disease involves also visceral organs, possibly the pancreas.

Severe lipemia, during diabetes mellitus, produces, not only in the skin but also in other organs, changes which are histologically very similar to those of xanthomatous disease. This kind of xanthomatous change occurring in the spleen and lymph nodes belongs also to the group of secondary xanthomata because the lipemia is the primary occurrence and the xanthoma cell formation is due to a secondary deposit in reticular cells and histiocytes. W. H. Schultze¹²¹ (1912) described first "large cell hyperplasia of the spleen during lipemia" and shows that little nests of xanthoma cells occur in the spleen as a result of lipemia in diabetes mellitus. Lutz,⁶⁷ Williams and Dresbach,¹⁵⁸ Pick,⁸⁴ Margaret Smith,¹²³ W. Schondorff,¹⁰⁹ S. Warren and Root¹⁴⁷ describe such large cell hyperplasia in diabetes with lipemia. We are inclined to classify the case which Lubarsch⁶⁶ described in 1918 under the title "Generalized Xanthomata and Diabetes" as the most outstanding example of this group of secondary xanthomatosis. This patient suffered and died of severe diabetes with lipemia. The liver, spleen, kidneys and especially lymph nodes and the walls of the lymph vessels exhibited large patches of xanthoma cells (lymphangitis xanthomatosis). There was no xanthomatosis of the skin but xanthosis of the skin was found. Xanthosis of the skin is almost always associated with the first group of primary xanthomatous diseases of the hypercholesteremic type (Cases 4, 6, 9, 11), but xanthosis of the skin has nothing to do with xanthoma formation.

Xanthosis, first described by von Noorden⁸¹ in diabetes mellitus, is a symptom which may occur without diabetes in all conditions of lipemia and even without lipemia if carotene is increased in the serum. The significance of the coincidence of hypercholesterolemia and hypercarotinemia is unknown. Xanthoma cell formation in the reticular apparatus was a secondary process due to lipemia similar to the more localized forms described in the spleen and in lymph glands. Certainly we cannot prove that Lubarsch's case belongs to this group of secondary xanthoma cell formation. However, the complete absence of skin xanthomata of both groups (xanthomata tuberosa and plana on the one hand and xanthomata disseminata on the other hand) while xanthosis was present, in addition to the clinical course of the disease is highly in favor of this assumption. We have already suggested above that Buerger and Grutz' cases of hepatosplenomegaly without jaundice but with extreme lipemia may belong to this group of secondary xanthomatosis resulting from lipemia. The lipemia in these cases is of unknown origin. Chronic cirrhosis of the pancreas may result in such extreme lipemia, but in contrast to the lipemia in diabetes mellitus, this lipemia condition is scarcely influenced by diets poor in fats. Attempts already made by different authors (Anitschkow,^{3, 4, 5} Kawamura⁵⁷ and McMeans⁷⁰) to reproduce xanthomatosis by the feeding of cholesterol, or to reproduce Gaucher's disease by intravenous injection of cerebroside (Kimmelstiel and Laas⁵⁹) and Niemann-Pick's disease by injection of phosphatides (H. Baumer and G. B. Gruber)¹⁴ lead to similar histological pictures in the spleen and lymph nodes as described by Schultze and others, as "large cell hyperplasia of the spleen during lipemia." It is evident that the reticular cells and the histiocytes are able to take up out of the blood, cholesterol as well as cerebroside and diaminophosphatides. In so doing, these cells change in appearance and assume the shape of foam cells. This procedure of injection of lipids, however, does not reproduce either the clinical syndrome or the complex anatomical picture of any of these "lipoid diseases," but it does reproduce histologically similar organic changes in the spleen, lymph nodes, and in extreme cases also in the liver (described by Schultze¹²¹ and others) to those that occur in association with lipemia in diabetes mellitus. It may well be that the mechanism of xanthoma cell formation in essential xanthomatosis is entirely different from the procedure which only attempts to increase the lipids in the blood by feeding or intravenous injection.

THE ETIOLOGY OF XANTHOMA FORMATION

The different clinical symptoms of essential xanthomatosis having been presented, the etiology of xanthoma formation in this systemic disease will now be discussed.

Waldeyer (1871)¹⁴⁶ considered the cells of xanthomata plana, afterwards called foam cells, to be embryonal cells which had the possibility of forming different kinds of fats and of releasing the fat by degeneration.

Virchow¹⁴⁵ described under the heading "xanthoma multiplex mulluscum lipomatoïdes," xanthomata disseminata of the skin as little benign neoplasms. Following the opinion of Virchow, xanthomata in general were considered in the literature to be "benign tumors." "*Ce sont donc les cellules endothéliales des espaces lymphatiques qui par leur prolifération, forment la tumeur xanthomateuse*" (classified as "endotheliome adipeux" by de Vincentis¹⁴³). Ponsgen,^{89, 90} Koebner⁹¹ accept the opinion of Waldeyer,¹⁴⁶ that cells which remained in an embryonal stage produced by their proliferation and adipose metamorphosis a so-called "embryonal lipoma" which is identical with the xanthomata. Torok¹³⁸ says that it is better not to classify xanthomata as true tumors but as abnormality of formation "*il (xanthoma) se forme du tissu a une endroit hétérotopique et il est constitué en raison même de cette heterotopie par des cellules adipeuses a évolution interrompue incomplète*" (embryonale).

Pinkus and Pick (1908)^{87, 88} found the fat substances in the xanthoma lesions to be doubly refractile lipids, cholesterol and cholesterol esters. These authors suggested that hypercholesteremia may be the genesis of xanthomatosis. "Cholesterol infiltration of certain cells takes place because of an increased cholesterol supply from the blood." This hypothesis was advanced after Aschoff^{3, 9} and his pupils had demonstrated that reticulo-endothelial cells were able to take up from the blood different kinds of dyes, as well as fat-like substances. Anitschkow^{3, 4, 5} in Aschoff's Institute found that by feeding rabbits cholesterol, foam-cells could be produced. On the other hand he was able to demonstrate that the same cells which changed to foam-cells also took up substances foreign to the body such as dyes. Indeed, these cells which have the characteristic of storing doubly refractile substances, as well as dyes, belong to those cells which Aschoff⁹ classifies as the reticulo-endothelial system. Because hypercholesteremia was believed to be essential for xanthoma cell formation it was natural to assume that the surplus of cholesterol in the serum due to a general disturbance of the cholesterol metabolism is taken up and stored by the reticulum cells, and results in a pathological change of the tissue forming xanthomata. This hypothesis is widely accepted in the literature. The proof, however, that there exists such a disease as a general metabolic disturbance of the cholesterol metabolism, which is the prerequisite of this assumption, is lacking. Appreciating this weak point of this hypothesis, Bloch¹⁸ and Schaaf¹⁰³ explain that cholesterol represents only one element in a very complex mixture of fat and lipids in the serum. "This mixture of lipid constituents does not exist in the serum in a dissolved form, but in the form of a finely dispersed emulsion. The normal proportion of all the lipid constituents must be maintained in the blood. If the proportion is changed in any direction, i.e. if the proportion of cholesterol to lecithin or to cerebrosides or sphingomyelins is altered, the result according to the laws of the colloid theory, is a disturbance in the stable aqueous lipid emulsion which the serum represents

The particles become coarser, the emulsion separates, and finally there is a precipitation of one or all of the individual constituents in the blood and tissues and a deposit of material, so that xanthomatosis results." This hypothesis of Bloch¹⁸ and Schaaf¹⁰³ has also as a prerequisite an extra-cellular general metabolic disturbance of the lipids, which results secondarily in a deposit of lipids in the reticular cells and the tissue. There is neither proof of a colloid decomposition of the serum or cell fluids resulting in precipitation nor any evidence that a disproportion of the lipids in the serum or tissue may lead to a flocculation of the colloid mixture. Deposits of lipids, especially cholesterol, are found in deteriorated tissue and in places where cells containing cholesterol undergo destruction. Up to the present we do not know of a spontaneous decomposition of a colloidal system of lipids in the serum even when the constituents of this system are markedly changed in their relation to each other. The colloid systems protected by different mechanisms in the organism are not to be compared with colloid systems prepared in the test tube because it is only partially and inadequately possible to copy the constituents of the colloid mixture in the body. The hypothesis of Bloch and Schaaf which adds to the assumption of extra-cellular disturbance of the lipid metabolism, a second hypothesis which has not been proved at all, does not stand critical analysis from the chemical point of view.

There remains to discuss as the main question, whether essential xanthomatosis is due to a general metabolic disturbance of cholesterol metabolism, which leads to an increased cholesterol supply to the reticular cells and a consequent storage of cholesterols and lipids in these cells (cholesterol infiltration of L. Pick^{85, 88}), or whether the metabolic disturbance is an intracellular metabolic disturbance confined to the reticular cells themselves, which may become xanthoma cells not by an increased supply but as the result of an intracellular metabolic disorder. The problem is, therefore, whether essential xanthomatosis is due to a disturbance of the intermediary cholesterol metabolism or whether it is caused by an intracellular metabolic disorder limited to certain reticular cells. Considering the mechanism of an intermediary disorder of the cholesterol metabolism, four possible processes of cholesterol metabolism may play a part.

(1) There may be a diminished disintegration of cholesterol in the intermediary metabolism. The xanthomata would then be the expression only of its retention and storage.

(2) There may be a diminished excretion and output of cholesterol and coprosterol in the feces. In such a case the xanthomata would be, as in the first process suggested, the result of retention and storage of cholesterol.

(3) The equilibrium between cholesterol and cholesterol esters may be disturbed so that sufficient cholesterol esters are not formed to transport an adequate amount of cholesterol. For the same reason the other lipids,

especially the phospholipids, may be involved and a disturbance of the lipid mixture may result

(4) There may be an increased synthesis of sterols. This increased synthesis may occur in organisms as a whole, and the sterols ubiquitously synthesized in the body are taken up out of the blood by reticular cells and stored. Or the increased cholesterol formation is performed by certain reticular cells which are able to synthesize and release cholesterol, but in the process as the result of an intracellular imbalance reticular cells assume the appearance of xanthoma cells. On the basis of the physiology of the intermediary cholesterol metabolism, which we have discussed earlier, we believe we are able to answer these four questions as to whether or not essential xanthomatosis is the result of a disturbance of the intermediary cholesterol metabolism.

The first assumption suggests a diminished disintegration of sterols in the intermediary metabolism. We have shown in our physiological discussion that there is no disintegration of cholesterol in the intermediary metabolism. Neither bile acids nor other sterols occurring in larger quantities in the organism are derivatives of cholesterol disintegration. The human organism is able to synthesize the sterol skeleton but cannot disintegrate it by means of fermentative processes.

In the second suggestion the question was raised whether a decrease of the cholesterol excretion could explain the essential xanthomatosis. Such an assumption should be easily answered by determining the cholesterol balance, but unfortunately the determination of cholesterol excretion in the feces cannot decide conclusively the cholesterol balance, because an uncontrollable amount of cholesterol may be destroyed by bacteria of the feces (according to Bertha Ottenstein). On the other hand, we have demonstrated that a diet free of animal sterols decreases the cholesterol content of the blood in cases of tendon xanthomata as well as in xanthomatous biliary cirrhosis. On the basis of an experiment carried out on a patient with tendon xanthomata where the total cholesterol dropped from about 800 mg per cent to almost normal values, Schonheimer and I have been inclined to believe that retention of sterols plays an important part in formation of xanthomata. The opinion was expressed that these patients behave like herbivorous animals, which can absorb but not excrete cholesterol. However, we had to change our minds because several of our patients (Cases 1 and 9) on a cholesterol-free diet showed insufficient reduction of the cholesterol in the serum, and we found that xanthomata tuberosa as well as tendon xanthomata were not altered even when the blood cholesterol had returned to almost normal values. The most important argument against the assumption that a disturbance of cholesterol output is the main cause of essential xanthomatosis is the fact that in the group of xanthomatous diseases characterized by xanthomata disseminata of the skin, involvement of the brain (diabetes insipidus), involvement of the bones, lungs and lymph

nodes, the cholesterol values in the serum were normal or high normal. Even in the other group, the hypercholesteremic type, which comprises xanthomata tuberosa and plana, tendon xanthomata, xanthomatous biliary cirrhosis, etc., we were able to find almost normal cholesterol figures (Cases 2 and 11) with beginning tendon xanthomata. A diminished output may play some rôle in the clinical course of essential xanthomatosis, but it is evident that this is not the main cause of this systemic disease.

The third possibility was a disturbance in cholesterol-ester formation or of a disproportion of cholesterol to phospholipids. In the literature and in our cases, the increase of total cholesterol, where there is an increase, is due to an increase of esters. The only exception to this finding of normal or high cholesterol esters in xanthomatosis was in patients with xanthomatous biliary cirrhosis where we found an inversed ratio of cholesterol to cholesterol esters in the serum. This is due to the liver damage and not to the xanthomatous disease (Thannhauser and Schaber¹³¹). The normal or high cholesterol esters in the blood and the high content of cholesterol esters in xanthomatous tissue show conclusively that there is no disturbance of ester formation which could cause difficulties in cholesterol transportation and lead to an abnormal deposit of cholesterol. Only in old granulomatous scar tissue of xanthomata, as in tendon xanthomata, free cholesterol prevails over ester-cholesterol, and sometimes crystallizes in the tissue. This tissue may have partially softened into a yellowish detritus. In the scars of these xanthomata foam cells are still scarcely found having been replaced by granulomatous tissue or softened to a yellowish, semi-fluid mass. Cholesterol esters are absorbed easier from such broken down foam cells while free cholesterol remains and crystallizes "in loco" (Figure 4, Case 1).

The figures for fat, cholesterol, cholesterol esters, monoaminophosphatides (lecithin and kephalin) and diamminophosphatides (sphingomyelins) of our series of cases are summarized here. These findings demonstrate that in xanthoma diseases of the hypercholesterol type, an increase of total cholesterol is usually accompanied by an increase in fat and monoaminophosphatides (lecithin and kephalin), while in the group of xanthomatous diseases of the normocholesteremic type, fat and monoaminophosphatides are also normal. We would like to infer from these figures that xanthomata formation is *not* caused by a disproportion of the lipid mixture in the serum, because in the group of xanthomata without an increase of cholesterol, the fat and monoaminophosphatides are normal, and in the group of xanthomata with high cholesterol, fat and monoaminophosphatide are increased proportional to the sterols.

The fourth suggestion deals with the question as to whether an increased cholesterol synthesis carried out everywhere in the organism and followed by a consequent storage of cholesterol in the reticular cells is the cause of essential xanthomatosis. Such an increased cholesterol synthesis as an expression of a general metabolic disturbance should lead in all clinical

Essential Xanthomatosis of the Normocholesteremic Type

| | | | | | | | |

syndromes of essential xanthomatosis to hypercholesteremia. Hypercholesteremia is, however, found only in one group of xanthomatous organ involvement, while the other group shows a normal amount of cholesterol, in spite of the fact that the same histological constituents are found in both groups. This is definitely against the assumption that xanthomata result from a general metabolic disturbance of cholesterol synthesis and favors the idea that we have to deal with a local cellular metabolic disturbance which may involve one organ only in a small area or groups of organs far apart.

In considering the four possible general disturbances of intermediary cholesterol metabolism discussed above, the following statements can be made. There is no definite proof to justify the assumption that primary essential xanthomatosis is caused by a disorder of the intermediary cholesterol metabolism. The generally accepted theory of L. Pick^{86, 87, 88} which suggests a general disturbance of the cholesterol metabolism followed by a secondary deposit of cholesterol in the reticular cells as the cause of essential xanthomatosis is untenable, since the experiments concerning the normal metabolism of cholesterol do not give the slightest evidence of an inter-

mediary disturbance of cholesterol metabolism. We would rather believe that the metabolic disturbance of the cholesterol is localized in those cells themselves which are called xanthoma cells after their content. Besides the reasons already mentioned, the experiments of Biedermann and Hoefer¹⁷ speak in favor of our suggestion of a localized cellular metabolic disturbance. These authors used tissue cultures of tissue prepared from xanthomatous nodules. They were able to demonstrate that the xanthoma cells of the cultivated tissue increased and emigrated. Some of the cells which had grown were identified as xanthoma cells by their content of doubly refractile substance.

It is evident from these experiments that the xanthoma cells themselves form the doubly refractile substance and a further proof for the genesis of xanthoma cells by an intra-cellular metabolic disturbance is added by the analogy which primary essential xanthomatosis bears to the other diseases of lipid metabolism, namely Gaucher's and Niemann-Pick's disease. In all three of these diseases large cells with fatty content arise in different organs. In essential xanthomatosis these cells contain cholesterol and other lipids. In Gaucher's disease these cells contain cerebroside, while in the Niemann-Pick's disease the content of these cells consists of diaminophosphatides (sphingomyelins). According to the suggestion of L. Pick, it was generally assumed that these three diseases were caused by the storage (infiltration) in the reticular cells of these lipids produced in excess by the intermediary metabolism of the organism. Concerning Niemann-Pick's disease, Baumann¹⁸ has already demonstrated that the content of total phospholipids (mono- and diaminophospholipids) is normal and even lower than normal in the blood. The sphingomyelins, however, are found in abnormal quantities only in the Niemann-Pick cells. In Gaucher's disease, Thannhauser, Reichel, Dameshek and Walcott [unpublished] were able to prove in four cases, that only traces of cerebroside were present in the serum of these patients, as is the case in normal serum. These investigations show that at least for Gaucher's disease, but probably also for Niemann-Pick's disease, the lipid substances involved in the particular disease are not formed in the intermediary metabolism and secondarily deposited in the reticular cells, but are formed and stored in the cells themselves. Gaucher's and Niemann-Pick's disease may, therefore, be considered as due to an imbalance of intra-cellular ferments (Thannhauser and Reichel^{18b}). We believe essential xanthomatosis, which belongs to the same group of lipid diseases, to be analogous to the above two diseases in that it is caused by an intra-cellular metabolic disturbance of certain reticular cells. In these cells cholesterol especially, but also other lipids, are found to be increased and stored, so that the xanthoma cells result.

In assuming a cellular disturbance to be the etiology of primary essential xanthomatosis, we return to the view of former investigators, Waldeyer,^{14b} de Vincentis,^{14c} Hallopeau^{46a} and Torok¹⁸⁸. According to these authors

the xanthoma cells are fat cells with embryonal qualities. With present day interpretations, we would say that these embryonal reticular cells, as far as their metabolism is concerned, are able to form *all* kinds of lipids. At that time the knowledge of metabolism was not sufficiently advanced to recognize the disorder which produced the xanthoma cell, as a cellular metabolic disturbance. The former assumption that the disorder is due to an embryonal metaplasia of certain cell groups is, however, identical with the idea that a cellular disorder is the cause of the disease "essential xanthomatosis."

To clarify further our interpretations of the mechanism of these cellular diseases, we may speak of essential xanthomatosis as "metaplastic reticular cholesterosis," of Gaucher's disease as "metaplastic reticular cerebrosidosis," and of Niemann-Pick's disease as "metaplastic reticular sphingomyelinosis."

The groups of secondary xanthomatous diseases are to be distinguished in principle from primary essential xanthomatosis (metaplastic reticular cholesterosis). In contrast to the primary essential xanthomatosis, which is a systemic disease resulting from an intracellular metabolic disturbance, the secondary xanthomatosis (eruptive form of xanthomata, formation of nests of xanthoma cells in the spleen, lymph glands and liver, large cell hyperplasia of Schultze) is a disease which is due to a storage of lipids which the reticular cells take up from the blood. An increase of cholesterol and other lipids in the serum as in lipemia during diabetes mellitus or as in lipemia of other origin, is the prerequisite of secondary xanthomatosis.

By suggesting that the formation of true xanthoma cells is due to an intracellular metabolic disorder of the reticular cells, we may explain the fact that xanthoma cell formation may occur independently of "essential xanthomatosis," as it does in localized tumors which have nothing in common with the systemic disease "essential xanthomatosis." Indeed, xanthoma cells are observed in different kinds of local tumors, such as fibrosarcoxanthomata, nevoxanthoendothelioma (Montgomery and Osterberg), etc.

As a result of the above study, and in order to clarify interrelationships between the type of xanthomata of the skin, and the various clinical patterns associated with each type, the following classification of xanthomatous diseases is offered.

CLASSIFICATION

- I *Primary essential xanthomatosis* (metaplastic reticular cholesterosis)
 - A Primary essential xanthomatosis of the hypercholesteremic type
 - 1 Xanthomata of tendons and tendon sheaths *
 - 2 Xanthomata tuberosa and plana
 - 2a *Forme fruste*
 - 3 Xanthomatous biliary cirrhosis resulting from xanthomatosis of the bile ducts

* The recent papers of van Bogaert and Epstein describe the combination of tendon xanthomata with xanthomatosis of the central nervous system. We are inclined to classify this new syndrome under the group of tendon xanthomata until more cases of this type have been analyzed.

- 4 Xanthomatosis of the endocardium and blood vessels
- 5 Eruptive form (if excessive lipemia is present) of skin xanthomata
- 6 Scattered nests of xanthoma cells in the spleen, liver and lymph glands (these may also be present in group B)

B Primary essential xanthomatosis of the normocholesteremic type

- 1 Xanthomata disseminata of the skin (localized all over the body, neck, axilla, bend of knees and elbows, groins, mouth and larynx)
- 2 Osseous xanthomata of the skull, scapula, pelvis, extremities and orbit
- 3 Xanthomatous involvement of pituitary and tuber cinereum with features of diabetes insipidus Xanthomata of brain, medulla and dura
- 4 Xanthomatous involvement of the lung and pleura with consequent pulmonary fibrosis
- 5 Scattered nests of xanthoma cells in the spleen, lymph glands and liver (these may also be present in group A)

C Primary essential xanthomatosis of the combined type (Cases of Hardaway, Weideman and Freeman, Weideman and Stokes)

II Secondary xanthomatosis due to lipemia

- 1 Eruptive form of xanthomata Xanthomata diabeticorum
- 2 Nests of xanthoma cells in the spleen, lymph glands and liver with and without hepatosplenomegaly (Schultze's large cell hyperplasia in the spleen during lipemia)
- 3 Xanthomatous lymphangitis (Lubarsch)

III Localized xanthoma cell formation in true tumors (Nevoxantho-endothelioma, fibrosarcoxanthoma, etc)

SUMMARY

- 1 The physiology of the cholesterol metabolism and its interrelationships with xanthomatous diseases is discussed
- 2 A critical review of the literature is presented
- 3 Twenty-two cases illustrating the different features of xanthomatous disease are described
- 4 On the basis of the above study, three different symptom-complexes of primary essential xanthomatosis are presented and differentiated and a classification offered Secondary xanthomatosis due to lipemia is distinguished from primary essential xanthomatosis
- 5 Xanthomatous biliary cirrhosis and its relation to xanthomatous bile duct disease is described

6 The eruptive form of xanthomata (xanthomata diabeticorum) is shown to occur not only in hypercholesteremia in diabetes mellitus, but also in xanthomatous biliary cirrhosis, xanthomata tuberosa and tendon sheath xanthomata if excessive hypercholesteremia is present

7 Xanthomata disseminata has been shown to be characteristic only of the second (normocholesteremic) group

8 It is shown that the general assumption that essential xanthomatosis is a storage disease of the reticular cells due to a disturbance of the general intermediary metabolism of cholesterol, is not in conformity with the physiological and clinical findings. Our studies suggest that essential xanthomatosis is a cellular disease of reticulum cells caused by an intracellular disorder of their cholesterol metabolism

CASE REPORTS

TORULA MENINGO-ENCEPHALITIS, A CASE REPORT *

By J HOMER CUDMORE, M D , F A C P , and JAMES R LISA, M D , F A C P ,
New York, N Y

SINCE the contribution of Freeman¹ on torula infection of the central nervous system, increasing attention has been paid to this interesting condition. Recently Levine² has again reviewed the literature, adding 17 more cases, including two of his own, bringing the total number to 60. The present case is reported, not so much because of the rarity of the condition but to add a new and as yet unreported manifestation of the infection, a cicatrizing lesion of the brain.

CASE REPORT

The patient, a white male 30 years old, was admitted to City Hospital on March 15, 1935, complaining of severe headache and abdominal pain.

Past History At the age of two years, he had scarlet fever. At 12, an enlarged cervical gland was diagnosed as tuberculous and treated by injection, possibly with an iodized oil. A biopsy, however, was not performed. At 14 and 16 there occurred attacks of pneumonia. From 26 to 28, he had severe epileptiform seizures which had continued in increasing frequency since then. He was drinking heavily when the seizures first appeared and they were attributed to this fact.

Present Illness One week before hospitalization, he began to have excruciating headache, the pain radiating from the eyes to the temporal regions. After three days, it was associated with vomiting. Both symptoms increased in severity to the time of admission. There were no other pertinent data.

Physical Examination He was a well developed and well nourished young man, extremely restless because of the headache. Mentally he was clear and cooperative. There was general hyperreflexia. Muscular, sensory and equilibratory tests were all normal. Abdominal reflexes were present. Pathological reflexes were absent. The pupils were equal, regular and reacted normally to light and accommodation. There were no ocular palsies. The fundi were normal. Except for a slight tachycardia, the other systems were entirely negative. The temperature was 99° F, pulse 60, respirations 20, blood pressure 110 mm systolic and 70 diastolic.

The blood count revealed a leukocytosis of 10,400 with 62 per cent polymorphonuclears and 38 per cent lymphocytes. The Wassermann reactions on blood and spinal fluid, colloid gold curve and urine were negative. Chemical examination of the spinal fluid showed sugar 72 mg per cent and chlorides 650 mg. Roentgenography revealed clouding of the right ethmoid sinus, marked sclerosis of the antral cells of the right mastoid and moderate sclerosis of the left antral cells, increased convolutional markings of the skull, and a greatly flattened sella turcica. The clinoid processes were not visualized. The pineal body was calcified.

From the First Medical Service and the Pathological Laboratory, City Hospital, Welfare Island, Dept Hospitals, New York, N Y.

Course The course was characterized by marked variability of the neurological symptoms. Periods of mental clarity alternated with drowsiness, severe headaches and nuchal rigidity. Vomiting occurred infrequently and was never of the projectile type. The neurological signs also varied. Occasionally there was a suggestion of facial fixity. Scattered, unequal and variable reflexes were described. At times there were a questionable right Babinski and absent right abdominal reflexes. At times there was a definite palsy of the left side including the face and the patient was unable completely to close the left eye. An eye consultant found both discs hazy and the retinal vessels tortuous, especially on the left, indicative of a moderate degree of intracranial pressure probably more localized on the left side.

FIG 1 The cicatricial lesion of the left parieto-occipital cortex

Spinal taps always relieved the headache and drowsiness, sometimes very quickly. On the last day he became very restless and irrational and resembled a hypomania. Death occurred suddenly.

Spinal Fluid Findings Twenty-one spinal taps were performed. Only once was the fluid somewhat cloudy, on the other occasions it was water-clear. The pressures varied greatly, ranging from 3 to 4 mm Hg to 46 mm. Usually it lay between 26 and 38 mm. The cell counts were always increased, from 78 on admission, to 340. Lymphocytes predominated, 75 per cent or over. Globulin was always present in traces. Except in the first specimen, sugar was absent. Cultures and

animal inoculations remained negative throughout the entire duration of the disease. Fortunately portions of many of the fluids had been saved in the laboratory, and after the autopsy, the cultures and animal inoculations were repeated. The results were the same.

The temperature curve was of a remittent character, gradually rising from 99° to 102.6° in 10 days, then slowly falling to 98.4° by the middle of April. From then until the end, the fluctuations were greater, more septic in type and reached 103.6°. The pulse was relatively slow and closely paralleled the temperature.

FIG. 2 The more compact lesion of the cerebrum showing the tuberculoid type of reaction. Torulae are present within and outside the giant cells.

Necropsy. The most prominent feature of the brain was the extreme edema and the enlargement of the right temporal lobe. In the cortex of the left parieto-occipital lobe was a small mass measuring 2 cm. in diameter, densely hard in consistence and resembling a healed tuberculous lesion. Over the base of the cerebrum, pons and medulla, the meninges were finely granular.

On section, the most prominent lesion was found in the region of the basilar nuclei. The entire region appeared completely disorganized by minute necrotic bright yellow foci. The entire brain appeared engorged and edematous.

Histology Sections were taken from the basilar nuclei, parieto-occipital regions, pons, medulla, cerebellum, choroid plexus and gasserian ganglia

The lesion of the left parieto-occipital cortex was formed by a confluence of dense fibrotic masses with a concentric formation. Some of the masses contained fine calcium deposit. Others had small necrotic centers with numerous polynuclear cells and masses of chromatin. In one region there were torula, apparently undergoing degeneration and staining intensely by the gram technic. At the periphery of the lesion was a compact zone of lymphoid cells and a rare giant cell.

The most extensive lesions were in the regions of the basilar nuclei. They were lytic in nature and contained torula in very large numbers. These lesions

FIG 3 The more diffuse type of lesion, lytic in nature, showing the complete disorganization of the tissue. Section taken from the basilar ganglia.

were not sharply delimited but involved the tissue diffusely. They merged into a more circumscribed lesion characterized by a tuberculoid reaction. Torula were present in these latter lesions both within and outside the giant cells.

The meningeal involvement was more intense over the pons and medulla than over the base of the brain. It was characterized by a tuberculoid reaction with numerous giant cells. The underlying tissue was involved by extension. Non-specific areas of degeneration with marked demyelination were prominent in the medulla.

The lesions of the choroid plexus and gasserian ganglia were similar to those of the meninges

Torula were present in profuse numbers, either free in the tissues or within giant cells. They were characterized by round, oval or egg shape, a single or double contour, frequently by spiked ends, and by budding. Staining reaction was variable. With hematoxylin and eosin, the capsules stained usually dark or light blue, sometimes with a narrow eosin-stained peripheral zone. With the gram stain, the heavier capsules stained intensely brown, the finer capsules red. The double contour frequently was much sharper with the gram stain than with hematoxylin.

Torula lesions of a tuberculoid nature were found histologically in the kidneys. All the other organs were negative.

FIG 4 The same region as figure 3, stained by the gram technic. This view shows the profusion of the organisms, their shape, the variability of reaction to the stain, the spiked ends and the budding.

COMMENT

The rapid course, the fever and the history of tuberculosis of cervical lymph nodes suggested in this case the diagnosis of tuberculous meningitis. The repeatedly negative results of animal inoculations, however, was a strong point against this diagnosis. Because of them, the possibility of torulosis was en-

tertaind The negative bacteriological results again prevented a correct diagnosis being made The failure to demonstrate torula in the cerebrospinal fluid is unusual, since most cases are positive, at least late in the disease That the results were due to discarding the cultures too soon, a point mentioned by Levine, does not apply to this case, since they were kept for a period of one month The inoculated animals were kept for two months before killing The first positive evidence was offered by the histological examination The most acute and youngest lesion was in the meninges

The chronic cicatrizing lesion of the cortex has hitherto been unreported in the literature That this lesion is due to torula is proved by the presence of organisms The odd persistence of the organism has also been observed by Weidman³ in experimental torulosis in the monkey Lesions which had spontaneously regressed and been replaced by scar tissue, still had demonstrable organisms In the present case, the cicatrix appears to be the only explanation of the epileptiform seizures which had occurred over a four year period

The history of cervical adenitis diagnosed tuberculosis is a further point of interest Unfortunately no biopsy was performed, so definitive pathology in this gland could not be decided That it may have been torula infection is possible A mistake in diagnosis of a cervical adenitis was reported by Wile⁴ Although in his case, Hodgkin's disease had been diagnosed, subsequent examination revealed that the lesion was due to torulosis

SUMMARY

A case of torula meningo-encephalitis is reported There was a history of epileptiform seizures extending over a four year period and a final acute meningo-encephalitic syndrome of seven weeks' duration simulating tuberculosis The diagnosis of torula infection was made at the postmortem table The pathological changes revealed all stages of torula infection and included a cicatrizing brain lesion, a hitherto unreported observation

EXANTHEM SUBITUM, REPORT OF A CASE

By MORGAN CUTTS, M D, *Providence, R I*

R C, a white female aged 31, was first seen on February 3, 1937, complaining of general malaise and weakness of one day's duration Three days previously she had returned from a week's trip to Texas, and had felt quite well until she noted chilly feelings, weakness, some headache and general malaise on February 2 She had no coryza, sore throat, aching in bones or joints, lachrimation, cough, or pain in

* Received for publication July 9, 1937

the chest, and she had taken no drugs of any kind recently. She had had both measles and rubella as a child, but not scarlet fever, and the remainder of her past history and family history was non-contributory.

On physical examination her temperature was found to be 102° by mouth, but apart from this there were no abnormal findings. Her throat appeared normal, and a throat culture was subsequently reported negative for hemolytic streptococci.

There were no Koplik spots, and no glandular enlargement. A leukocyte count done later the same day was 3,200 with approximately 50 per cent polymorphonuclears. It was remarked at the time that she was surprisingly free of symptoms, as the slight malaise she had complained of had been completely relieved by 32 mg of codein and 0.6 gm of aspirin. Her temperature remained elevated between 100° and 102° for three days, without the development of any other symptoms, after which it suddenly dropped to normal and there appeared at the same time a measles-like rash, in places confluent, over the neck, body, and upper arms. This in turn faded after 24 hours and had completely disappeared in two days. There was no subsequent rise in temperature, and the patient was discharged with a diagnosis of *exanthem subitum*. Several days after recovery her white blood cell count was found to be 7,600.

Zahorsky¹ first clearly described this disease in 1910 and 1913 under the name of *roseola infantum*, and Vieder and Hempelmann² in 1921 suggested the name of *exanthem subitum*.

A recent article by Zahorsky³ clearly describes the typical course of this disease in infants and children. One attack usually confers immunity, and only rare instances of infection of one child by another have been observed. The incubation period is believed to be 8 to 14 days. Fever lasts for approximately four days and falls suddenly, at which time the rash appears, first on the back and abdomen, and rapidly spreads to involve most of the body. Constitutional symptoms, such as restlessness, headache, and gastrointestinal disturbances, may be more or less marked, but are rarely severe. Leukopenia is a constant finding, and affects chiefly the cells of the granular series. No complications have been observed. No previous report of a case occurring in an adult could be found in the literature.

As in the case here reported measles, rubella, and scarlet fever can generally be ruled out fairly easily, especially by the typical time relationship of the fever and rash. The absence of any severe symptoms or of a second rise in fever also speaks against dengue, which was a definite possibility in this case, and is mentioned by Zahorsky as a possible source of error.

A CASE OF CARCINOMA OF THE ISLANDS OF LANGERHANS WITH HYPOGLYCEMIA^{*}

By HENRY JOACHIM, M D, F A C P, and MORRIS M BANOWITCH, M D,
F A C P, *Brooklyn, New York*

THE syndrome of spontaneous hypoglycemia described by Seale Harris¹ was attributed by him to hyperinsulinism. Since then this conception has been amply confirmed by numerous reports in the literature, and particularly demonstrated by Wilder, Allan, Power and Robertson² in 1927. They reported a case of carcinoma of the islands of Langerhans with liver and lymph node metastases, the extract of which was found capable of lowering the blood sugar in rabbits.

In the past 10 years numerous cases of spontaneous hypoglycemia due to tumor formation have been reported but the great majority have been due to hyperfunctioning of adenomas of the islands of Langerhans. Islet carcinoma causing this syndrome has been relatively rare. There have been seven cases (Wilder² et al., Hamdi³, Judd, Faust and Dixon⁴, Bickel, Mozer and Junet⁵, Cragg, Power and Lindem⁶, Howland, Campbell, Maltby and Robinson⁷, Graham and Womack⁸). To these we wish to add a case of spontaneous hypoglycemia due to islet carcinoma.

CASE REPORT

The patient was a female, aged 31, housewife by occupation, who was admitted to the Beth Moses Hospital April 4, 1935 and died May 27, 1935. The chief complaint on admission was of convulsions for the preceding three days, followed by coma eight hours prior to admission.

The family history was essentially negative except that one sister was suffering from encephalitis. Patient had given birth to five children, all living and well.

Eleven years before, following childbirth, she had developed salpingitis from which an uneventful recovery had taken place with no operative interference. Otherwise patient had never been ill.

For the past four years the menstrual periods had been somewhat irregular and she had noticed that her bleeding had increased.

The present illness began three days before admission when suddenly the patient began to sweat profusely. This was followed by convulsions which involved the entire body, and which were followed by comatose periods of varying duration. On awakening she would remember nothing. During the three day period she had numerous such attacks, the last attack commencing at 4 p m on the day of admission to the hospital, at 11 p m the patient was still in coma.

In checking back the history we received the following information. Four weeks prior to admission the patient had fallen down a flight of stairs and since that time had complained of headaches and had experienced several fainting spells.

On admission the patient was comatose. She was well nourished with some tendency towards obesity. There was no evidence of any cranial nerve palsies, no rigidity of the neck. The heart and lungs were essentially negative, the liver and spleen were not felt. After the patient had come out of coma, there was definite tenderness noted above her umbilicus and somewhat to the left, but no definite masses were palpated.

The temperature on admission was 99.8°, pulse 100, respiration 22. Blood pressure 130 systolic and 70 diastolic. Examination of the urine was negative. The

* Received for publication July 31, 1937

blood sugar, taken immediately on admission and before the administration of glucose was 30 mg per 100 c c

A diagnosis of hypoglycemic shock secondary to hyperinsulinism, was made. At that time the possibility of adenoma of the pancreas as an underlying pathological factor was considered.

Intravenous administration of 50 per cent glucose brought the patient out of coma quickly.

For the next two days the patient had no attacks, but, on April 5, at 12 30 a m, she lapsed into coma. Intravenous glucose was given and the patient responded well. The third attack occurred on April 6, at 6 28 a m, the patient again passed into coma, intravenous glucose was given, but the response was not as dramatic as on the first administration. The blood sugar at this time was 25 mg per 100 c c. The patient remained in fairly good shape without any attacks until April 11. During this period she received glucose frequently by duodenal tube and in her diet. Her blood sugar remained at 70 mg. Another hypoglycemic attack occurred on April 12 during which her blood sugar fell to 25 mg.

On April 8 a glucose tolerance test was carried out. Specimens were taken every 15 minutes from 10 45 a m to 4 45 p m.

Sugar Tolerance Test

| | |
|--------------------------|-----------------------------------|
| 10 45 Blood sugar 120 mg | (100 grams of glucose were given) |
| 11 05 Blood sugar 125 mg | 1 10 Blood sugar 75 mg |
| 11 20 Blood sugar 130 mg | 1 30 Blood sugar 65 mg |
| 11 35 Blood sugar 150 mg | 2 00 Blood sugar 65 mg |
| 11 50 Blood sugar 65 mg | 3 15 Blood sugar 60 mg |
| 12 05 Blood sugar 65 mg | 3 45 Blood sugar 50 mg |
| 12 15 Blood sugar 60 mg | 4 15 Blood sugar 70 mg |
| 12 30 Blood sugar 60 mg | 4 45 Blood sugar 75 mg |
| 12 50 Blood sugar 70 mg | |

Because of the repeated attacks of coma the patient was transferred to the surgical service for operative interference. On April 15 exploratory laparotomy was performed by Dr. Harold Rabinowitz, and the findings were as follows:

The liver, gall-bladder, stomach and duodenum were normal. Along the lesser curvature of the stomach a hard indurated gland could be felt, the size of a pea. In the terminal half of the pancreas a hard irregular and nodular mass about the size of a tangerine orange and several large glands were palpated. The vessels of the spleen seemed to be buried in the mass at the tail end of the pancreas. The spleen had to be removed in order to get at the mass in the pancreas. Only part of the neoplasm could be removed. The patient's immediate postoperative reaction was good.

The pathological report was as follows:

Gross The specimen consists of a spleen and two small portions of pancreatic tissue. The spleen weighs 170 grams. It is moderately firm and rubbery in consistency and on cross section presents a homogenous reddish-brown appearance. The trabecular markings are distinct. The follicles are indistinct. The masses of pancreatic tissue reveal firm, discretely circumscribed, golden-yellow nodules, ranging from 3 to 7 mm in diameter. They are firm in consistency, and in the second portion of tissue removed reveal some degree of invasion of the surrounding normal lobules of pancreas, which are of a more grayish-tan color. In this portion of tissue, there is a discretely circumscribed structure, apparently a lymph node, measuring 7 cm in length, and 1 cm in diameter. Cross section reveals a pearly-gray appearance with a thin rim of lymphoid tissue surrounding the pearly-gray nodular mass. The portions of tissue removed are too small for biochemical assay.

Nests of polygonal cells with large clear nuclei are present. The latter have well-formed nuclear membranes and contain a nucleolus. The nuclei vary considerably from clear vesicular structures to large hyperchromatic nuclei with coarse

FIG 1 (*above*) Island cell carcinoma in the pancreas (low power)
FIG 2 (*below*) Island cell carcinoma in the pancreas (high power)

chromatin clumps. The nests are covered with a layer of syncytial-like cells. Aniline-fuchsin-methyl green stains reveal only a few green granules in the cytoplasm, whereas the islets in the normal portion of pancreas contain red and green granules. The cytoplasm is dust-like and contains numerous vesicular structures.

A lymph node contains nests of similar cells

The spleen reveals sinus hyperplasia and distention. The follicles are somewhat compressed. The sinus reticulum is hyperplastic.

Diagnosis Carcinoma of the pancreas with lymph node metastasis. Chronic passive congestion of the spleen.

For the first four days after operation glucose was administered frequently by duodenal tube and vein. The patient was free from attacks of coma. However, on April 19 another episode of sweating, convulsion and coma took place, and, from then on these attacks kept recurring daily so that on April 29 there were only traces of sugar in her blood. From then on the attacks of sweating and twitching recurred frequently in spite of almost continuous glucose administration. The glucose became less effective and the patient expired May 27.

Additional laboratory findings were: Wassermann and Kahn tests were negative. Her blood count on admission was: Hemoglobin 90 per cent, red blood count 4,100,000, white blood count 15,200, polynuclears 64 per cent, lymphocytes 36 per cent. Prior to her death blood count was as follows: Hemoglobin 50 per cent, red blood count 3,000,000, white blood count 40,000, polynuclears 85 per cent, lymphocytes 15 per cent.

The response to adrenalin injection was as follows:

| | | |
|-------|-------------------------------------|-------|
| 10 42 | Blood sugar | 70 mg |
| 10 45 | 10 minims of adrenalin was injected | |
| 11 01 | Blood sugar | 60 mg |
| 11 20 | Blood sugar | 55 mg |
| 11 40 | Blood sugar | 60 mg |
| 11 50 | Blood sugar | 55 mg |
| 12 00 | Blood sugar | 45 mg |

At this time patient was sweating, apathetic, twitching, and glucose had to be given.

A roentgenogram of the patient's skull revealed the presence of a definitely small sella turcica which was morphologically normal.

The urine was repeatedly negative, except on occasions when traces of sugar were found, probably as a consequence of the glucose injections.

DISCUSSION

Since the new era in the treatment of diabetes was initiated by the discovery of insulin, the more common use of blood sugar determinations has revealed the frequent presence of a diminution in the normal amount. The normal limits on a fasting stomach vary from 80 to 110 mg per 100 cc of blood, the limits depending upon the method used in the determination. Low blood sugar readings of 70 mg or less may depend upon an excess of insulin therapeutically administered or spontaneously secreted by the islets of Langerhans. For this latter type Seale Harris coined the name of hyperinsulinemia in 1924. Since then many cases of this condition have been observed. Wilder of the Mayo Clinic was the first in 1927 to establish the causal relationship of tumors of the islet cells, insulomas, to hypoglycemia due to hyperinsulinemia. There are other causes of hypoglycemia not dependent upon structural changes of the islets of Langerhans. From a clinical standpoint a persistent spontaneous hypoglycemia is still not generally recognized by the profession and hypoglycemic states masquerade under the picture of a multitude of diseases.

The normal blood sugar is the balance resulting from the liberation of stored glycogen from the liver into the blood stream as glucose, and the withdrawal of some of this glucose from the blood for tissue deposit and utilization. The difference between the arterial and venous blood sugar is equivalent to that abstracted from the blood for tissue storage or consumption.

Hypoglycemia is present in starvation and states of inanition caused by malignancy, in prolonged fever, excessive vomiting, diarrhea, celiac disease, sprue, extensive hepatic damage, prolonged muscular activity as in forced military marches, Addison's disease, other states of hypoadrenia as after extensive burns, adrenal hemorrhages or toxic adrenal depression as from diphtheria or sepsis, in cases of myxedema, progressive muscular atrophy and myasthenia gravis. In pituitary hypofunction (Simmonds disease) the blood sugar may be extremely low. New-born infants delivered from diabetic mothers may suffer from hypoglycemia as a result of a prenatal compensatory islet hyperplasia to supply the necessary maternal insulin. Hypoglycemia is a characteristic feature of von Gierke's disease.

In discussing the symptoms we are not taking into consideration the acute hypoglycemic states induced by the administration of excessive doses of insulin. We are at present concerned with chronic spontaneous hypoglycemic states.

The most frequent symptom is fatigue and easy exhaustibility, often dissipated by a meal rich in carbohydrates. Extreme hunger, absence of satiation and a constant feeling of emptiness, with a sinking sensation, vertigo, irritability and an excitability resembling that of alcoholism have been observed. Nausea and vomiting may occur. Tremors are often present. The pulse may be rapid and the blood pressure may be low though it is sometimes elevated. Convulsive seizures, diplopia, transient attacks of aphasia and hemiplegia may be due to hypoglycemic states. Hyperhidrosis may occur. Some patients complain of a constant chilliness. Insomnia is a frequent symptom. The first evidence of hypoglycemia may be coma. Attacks of angina pectoris may be precipitated by hypoglycemia. The basal metabolism is low.

SUMMARY AND CONCLUSIONS

A case of spontaneous hypoglycemia is reported in which the entire syndrome ran its course in two months. At operation a tumor of the pancreas which proved to be a carcinoma of the islets of Langerhans was found. There were numerous lymph node metastases, and as far as could be determined no metastases of the liver were present. No autopsy was obtained. There were no attempts to demonstrate the presence of insulin in the tumor tissue. However, in view of the cases reported by Wilder et al. and Cragg et al., we believe that we are justified in classifying this case as one due to true hyperinsulinism.

EDITORIAL

ADVANCES IN THE TREATMENT OF PELLAGRA

THE success of Goldberger and his associates in experimentally producing pellagra in man and its counterpart, black tongue, in dogs proved that a dietary deficiency plays an essential part in the production of these diseases. His demonstration that yeast, liver, and other foods rich in vitamin B₂ (G) prevents and usually cures the disease indicates that the active substance is probably to be found in some portion of the vitamin B₂ complex.

Certain facts, however, have led some investigators to believe that other factors are also concerned in the development of the disease. It seems probable that some individual predisposition must exist. The disease, at least in its outspoken forms, appears only in a relatively small portion of a community whose diet seems significantly deficient. Furthermore, a patient with outspoken pellagra may recover without specific treatment while on a diet like that of Goldberger, which is markedly deficient in B₂ although it does not lack this entirely. Thus in a series of 107 cases of pellagra reported by Ruffin and Smith,¹ 30 recovered completely while on such a diet before any treatment was given.

The suggestion has been made that there is a lack of some intrinsic factor also in susceptible individuals. Thus Sydenstricker and Thomas² believe that there is a deficiency of gastric secretion analogous to, but different from, that found in pernicious anemia. They reported lasting improvement in several patients who were kept on a deficient diet and treated only by the administration of normal gastric juice, and suggested that the effectiveness of the latter was due to the fact that it made possible the efficient utilization of the small amounts of "extrinsic factor" (in the B₂ complex) present in the diet.

The injurious effect of exposure to sunlight has also been emphasized.³ There is no doubt that sunlight may precipitate an attack of pellagra and aggravate the dermatitis, and that it may cause a relapse in inadequately treated patients. However, sunlight alone will not cause the disease, nor will protection from exposure always prevent its development.

The observations of Goldberger justified the hope that relatively simple dietary measures would prove effective in both preventing and curing the disease. Thus far, however, the results obtained are rather disappointing. Although the incidence of pellagra in the United States has diminished, it is still far too prevalent, as is indicated by the mortality rate of over 3000 deaths annually, reported to the United States Public Health Service. Fur-

thermore, the therapeutic procedures which have been generally employed have not proved successful in the severer cases. Thus Spies, Chinn and McLester⁴ reported an average mortality rate of 32 per cent in the Hillman Hospital in Birmingham, Alabama. These unsatisfactory results, however, were probably due in part to inadequate treatment. These investigators were able to reduce the mortality rate in a series of 73 cases of endemic pellagra to 7 per cent by giving larger quantities of food and much larger doses of yeast and liver, provided a sufficient staff of nurses was available to insure that the quantities prescribed were actually consumed.

The effectiveness of liver in the treatment of pellagra has led to the investigation of the therapeutic activity of various types of liver extracts. One of the most careful studies is that of Ruffin and Smith,¹ based on 77 cases who failed to improve while on the basic (deficient) diet. They found that a relatively crude unconcentrated extract for oral administration in pernicious anemia (Valentine's, N N R) was highly potent in curing pellagra, but that the use of concentrated extracts by parenteral channels was definitely less satisfactory. Following the administration of large doses at frequent intervals, in most cases the stomatitis subsided within a few days, and some general improvement followed. Usually, however, either recovery was only partial, or relapse followed quickly after exposure to sunlight. If the oral extract was fractionated by the addition of alcohol, neither the filtrate (which contains most of the pernicious anemia principle) nor the precipitate, if administered individually, gave satisfactory results. The administration of both simultaneously, however, was highly effective. This observation, if confirmed, would indicate that two substances are concerned.

The substance or substances which are required to prevent pellagra are not yet definitely known. Several substances with different physiological properties have been isolated from the vitamin B₂ complex. Of these the best known is riboflavin (lactoflavin), a fluorescent dye which plays an important part in the oxidation-reduction reactions in all the body cells. Although a deficiency of this substance causes disease in rats, symptoms due to a deficiency in man have not been recognized, and its administration does not cure pellagra. The same appears to be true of the fraction vitamin B₆, lack of which causes a dermatitis in rats, and probably of the "filtrate factor."⁵

In September 1937, Elvehjem et al.⁶ reported the isolation of nicotinic acid amide from liver extracts which were effective in curing black tongue in dogs. They found that this substance, as well as commercial preparations

⁵ JUKES, T. H., and LEPKOVSKY, S. Distribution of "filtrate factor" (water soluble vitamin belonging to vitamin B complex and preventing dietary dermatitis in chicks) in certain feedings, *Jr. Biol. Chem.*, 1936, **CXLIV**, 117-121.

⁶ ELVEHJEM, C. A., MADDEN, R. J., STRONG, F. M., and WOOLEY, D. W. Relation of nicotinic acid and nicotinic acid amide to canine black tongue, *Jr. Am. Chem. Soc.*, 1937, **lix**, 1767.

of nicotinic acid, promptly cured the black tongue. This observation led at once to the trial of nicotinic acid in the treatment of human pellagra, and several reports as to its effectiveness are already available. Spies, Cooper and Blankenhorn⁷ in November 1937, reported the successful treatment of several cases, and recently⁸ have reported the results obtained in 11 cases in all. These investigators (as a rule) kept their patients for one to three days on a deficient basic diet, to exclude a spontaneous improvement, and then treated them with nicotinic acid for one to three days. Subsidence of the glossitis and stomatitis was utilized as evidence of the effectiveness of the treatment, and this was manifested dramatically in every case within 24 to 72 hours. Most of the patients, because of the severity of their illness, were then also given the usual routine treatment for pellagra, so that their observations do not prove how effective nicotinic acid alone would be in curing the other manifestations of the disease. However, Smith, Ruffin and Smith⁹ have reported one case, and Fouts et al.¹⁰ have reported four cases of pellagra who were kept on a deficient diet and treated with nicotinic acid alone. Recovery in all cases appeared to be complete and as satisfactory as that obtained with liver extract, except that the dermatitis subsided more slowly.

The dose of nicotinic acid and the mode of administration varied greatly, and within limits appeared to be immaterial. From 0.15 to 1.0 Gm was given by mouth daily in divided doses, or in some cases from 30 to 60 mg intravenously or from 50 to 100 mg by hypodermoclysis. The larger doses caused transient sensations of heat, flushing and tingling of the skin, but no untoward reactions were noted.

The exact relation of nicotinic acid to pellagra has not yet been established, but the evidence strongly suggests that it may prove to be the pellagra-preventive factor of Goldberger. It seems certain to prove a very valuable aid in the treatment of the disease, particularly in the severe cases. Until its effectiveness and its limitations have been more precisely determined, it should be used with due caution, and as a supplement, rather than a substitute for the usual measures of treatment. The cheapness of nicotinic acid would also make practicable its use as a prophylactic measure, if further study shows that it is safe and effective for this purpose.

REVIEWS

The Practitioner's Library of Medicine and Surgery Supervising Editor, GEORGE BLUMER, M A (Yale), M D, F A C P, David P Smith Clinical Professor of Medicine, Yale University School of Medicine, Consulting Physician to the New Haven Hospital *Supplement and Index Volume* xlv + 1161 pages, 177 illustrations D Appleton-Century Company, Inc, New York 1938 Price, \$10 a volume

The unnumbered *Supplement and Index* volume, which completes *The Practitioner's Library of Medicine and Surgery*, is the thirteenth in the series. The first of these was given notice in the ANNALS in 1932, and a brief description of each of the succeeding volumes has appeared in these columns. In the present volume the supplemental section comprises 808 pages, and to it 67 authors have contributed. In general, the topics have been arranged in the order of presentation in the preceding volumes with subdivision into sections accordingly. The material presented consists in part of a fuller or modernized treatment of topics already included in earlier volumes. The excellent chapter on The Symptoms, Diagnosis and Treatment of Trichinosis is illustrative of this group. It is a much needed addition to the overly compressed discussion of this subject in Volume III. To a considerable degree the Supplement deals with newer disease concepts, some of which will be found presented here in textbook form for the first time. Meloidosis, Rift Valley fever, onchocerciasis, radium poisoning, calcinosis, glycogenosis, regional ileitis, liver deaths in surgery and the Laurence-Moon-Biedl syndrome are examples of newly defined or recently restudied diseases which are discussed authoritatively. Other important chapters deal with the newer work on the ductless glands and sex hormones, blood chemistry, Boeck's sarcoid, drug reactions, staphylococcic food poisoning, hypoglycemia, pulmonary carcinoma, various hereditary dysplasias, protamine insulin, artificial fever therapy, sympathectomy for vascular disease, sexual impotence in men and the psychological aspects of pediatric practice. To the practitioner with a keen interest in the newer developments in the entire field of Medicine, this volume will prove the most interesting and valuable of the series. The general index, which follows the new textual material, extends over 350 pages. It is not simply a combination of the individual volume indexes but a new compilation, which has made possible a full and logical division of each topic. The reviewer has tested it in various respects and it appears to be unusually adequate. To the supervising editor and his assistants, congratulations are due for the successful completion of the *Library*. It has been a huge task. With the success of the present Supplement in mind, we hope that other supplemental volumes will be forthcoming in order that the *Library* may be kept continuously abreast of the most advanced medical thought of proved value.

C V W

Diseases of the Skin By FRANK CROZER KNOWLES, M D Third Edition, thoroughly revised 640 pages, 16 X 24 cm Lea and Febiger, Philadelphia 1935 Price, \$6 50

The author has presented a text whose chief value both to the student and to the practitioner of medicine lies in the excellent clinical descriptions presented of cutaneous diseases, and of those systemic diseases which have cutaneous manifestations. Dr Knowles has made every attempt to present in a concise manner, in simple

language, a word picture of skin diseases that can be readily understood. He has devoted one chapter to the subject of diagnosis, in which in semi-tabular form he has listed the sites of predilection, and configuration of the commoner skin diseases. The chapter on therapy is an excellent guide in prescribing treatment for patients, radium, roentgen-ray and actino-therapy are all discussed briefly but clearly. The reader is made to feel that dermatology is not a thing apart but that it is an integral part of medicine.

H. M. R., JR.

Clinical Laboratory Diagnoses. By SAMUEL A. LEVINSON, M.S., M.D., and ROBERT P. MACFATE, Ch.E., M.S. 877 pages, 14.5 × 23.5 cm. Lea and Febiger, Philadelphia. 1937. Price, \$9.50.

The authors have reviewed the pertinent subject matter of anatomy, physiology, biochemistry and pathology at the beginning of each main division of clinical pathology. Such treatment is of necessity too brief and incomplete to be of value for reference though of aid to the student in review. The occasional brief comments on methods of treatment might better have been omitted.

In addition to comprehensive sections on the analysis of gastric and duodenal contents, feces, urine, sputum, blood chemistry, hematology, immunology and serology, spinal fluid, general bacteriological procedures, histological technic, and the metabolism test there are chapters not often included in similar volumes. These unique sections deal with the laboratory methods in pediatric procedures, legal medicine and toxicology, skin tests and biological tests and a 59-page appendix dealing with the conduct of a course in clinical pathology. This appendix is of value to those interested in teaching the subject.

Few clinical pathology textbooks include such a wide variety of material pertaining to the laboratory. There are very few omissions of important material—the technic for the detection of Bence-Jones protein in the urine being one.

J. H. M.

Manual of Psychiatry and Mental Hygiene. By AARON J. ROSANOFF, M.D., University of Southern California. 1091 pages. John Wiley & Sons, New York. 1938. Price, \$7.50.

This seventh revised edition is one of the first books on psychiatry to come off the press in 1938, and is surprisingly up-to-date. Recent research in this specialty is presented, and generally accepted views are synthesized into a working manual of diagnosis, prevention, and treatment. The case method is used to clarify each subject discussed.

The volume is divided into six parts. Part I presents the neuropsychiatric syndromes and their etiology. Part II presents in detail the individual pathological conditions found. Part III is devoted primarily to therapeutics, and Part IV to prevention or mental hygiene. Part V gives the various special diagnostic procedures that need to be referred to continually in psychiatric practice, and Part VI gives several supplementary aids, which make the volume complete as a reference book.

This book has stood the test of time, and in this rewritten form the internist will find much valuable advice that he is constantly being called on for. Psychiatry has made many developments during the past ten years, and Rosanoff appears to have missed nothing.

J. L. McC.

A Method of Anatomy By J C BOILEAU GRANT, Professor of Anatomy in the University of Toronto lxvii + 650 pages William Wood & Co, Baltimore 1937 Price, \$6 00

There are no textbooks of human anatomy in English which combine adequate descriptive treatment with a clear explanation of mechanical function. All contain details which should enable an experienced anatomist to deduce the functional design of a given part or region, but the treatment is mainly concerned with a description of systemic anatomy, functional analysis of the whole organ or region being confined to generalities in small print. The so-called "applied anatomies" do not meet this need, for they are primarily designed to introduce the surgical approach. For the architectonic principle of structure one must turn to the works of Fick and Braus, which unfortunately are not available in translation.

Professor Grant has perceived this divergence in the modern development of anatomy and has sought to restore the attitude which became prevalent with Borelli's *De motu animalium*. His 'method' is essentially that of regional anatomy as exemplified in a good dissecting manual with the difference that it goes on to clarify the region in terms of functional adjustments. Wherever comparative and developmental anatomy can serve to establish a particular line of evidence they are aptly drawn upon.

The treatment of the acromio-clavicular joint may be quoted in part to illustrate the application of the deductive principle. "The *conoid* and *trapezoid ligaments*, into which the *coraco-clavicular ligment* is subdivided, resist such a force [a fall on, or a blow applied to, the edge of the acromion], it is their duty to hold the scapula laterally and to prevent it from being driven medially. If this be true, their fibers must obviously pass medially and downwards which they do. If they are to retain the scapula in position they could obviously take no other direction."

The section on the abdomen, especially with regard to the peritoneal relations of the viscera, is the most comprehensible to be found in an English text. The *situs viscerum* is presented with a clear account of the developmental events leading up to it in a manner quite similar to that of Braus in *Anatomie des Menschen*.

There are 564 line drawings which drive home the deductive principles of the text in a peculiarly forceful way. They make no pretense of being rigidly factual, they serve rather the function of the lecturer's blackboard diagram.

The system of nomenclature used is the Birmingham Revision of B N A with the standard B N A equivalents usually given in parentheses. Whether this feature is an advantage or a defect from the point of view of American anatomy remains for the future to say.

On the whole the book is to be highly recommended for teachers and students alike. It can not be considered in any way to supplant the standard reference texts, but can be used with them as a valuable adjunct to acquiring a conception of the human organism as a whole.

J C L

The Colon as a Health Regulator—From a Surgeon's Point of View By SIR HENRY M W GRAY, K B E, C M G, L L D (Aberdeen), M B, C M (Aberdeen), F R C S (Edinburgh) 100 pages, 13 × 20 cm The Macmillan Company of Canada, Ltd, Toronto 1936 Price, \$2 50

The author subscribes to and enlarges upon the thesis that colonic stasis, stagnation and putrefaction, the consequence of bands, kinks, adhesions and other abnormalities are frequent causes of vague abdominal symptoms and chronic ill-health.

Many patients, so ailing but giving none of the manifestations of the more obvious abdominal diseases, are in reality suffering from definite organic lesions, the presence of which most surgeons do not suspect, much less operate upon. Gray accepts in part the speculations of Lane but advances the hypothesis that most if not all kinks and adhesions are developmental abnormalities, the result of faulty descent of the cecum with irregular and imperfect fixations of the large gut. Cause and effect were confused by the older theorist.

The symptoms are many and varied, ranging from constipation, abdominal pain, nausea and vomiting to loss of weight, anemia, acneiform eruptions, nervous and "rheumatic" manifestations. The diagnosis is arrived at by the elicitation of some quite unusual and unorthodox physical signs.

The correction of the condition is accomplished by means of an unusual operation termed a "spring-cleaning" which combines the releasing of kinks and adhesions with the fixation of abnormally mobile portions of the large gut through a long laparotomy incision, done according to the author's formula. Justification for and recommendation of this operation form the main theme of the monograph.

Difficulty in preoperative recognition and selection of suitable cases may cast some doubt upon the desirability of routine adoption of such a procedure. Although there is a very low mortality rate and evidence of some immediate benefit, more convincing proof of its efficacy could be arrived at by a long follow-up of cases, which is not supplied.

Dr Abraham S Rubnitz (Associate), Omaha, Nebr—5 reprints,
Dr Frederick W Williams (Associate), New York, N Y—1 reprint

Acknowledgment is also made of the receipt of a copy of the new "Navy Directory," January 1, 1938, from the Bureau of Medicine and Surgery, and of a reprint, "A Portrait Gallery of Physicians—The Collection in the Army Medical Library," by Col Harold Wellington Jones (MC), U S A

Acknowledgment is also made of a gift to the College Library of a book of poems by Emilie Conklin, Indianapolis, Ind, entitled, "Doctors, I Salute!"

NEW LIFE MEMBERS

The following Fellows have been entered, upon their subscriptions, as Life Members of the American College of Physicians, at the dates indicated, making a total of ninety-eight

Dr Charles Ricksher, Norwich, Conn, February 1, 1938
Dr Floyd H Lashmet, Petoskey, Mich, February 11, 1938
Dr John Paul Ritchey, Missoula, Mont, February 14, 1938
Dr James F Churchill, San Diego, Calif, February 14, 1938

COMMITTEE ON GRADUATE EDUCATION AND INTERNAL MEDICINE

In accordance with directions embodied in the following resolution of the Board of Regents, December 12, 1937, Dr J H Means, President, has appointed the following Committee

"Resolved, that the Board of Regents authorize the appointment of a committee by the President of a size which he may select, not necessarily confined to members of the Board of Regents, but to be designated as a committee of the Regents, on the whole question of graduate education and internal medicine"

Dr William J Kerr, San Francisco, Chairman
Dr Charles H Cocke, Asheville
Dr Hugh J Morgan, Nashville
Dr Charles S Burwell, Boston
Dr Joseph A Capps, Chicago

It is intended that this committee shall supervise graduate courses in medicine arranged by the College for its members, and that the committee will also collaborate with other national committees, when and if its advice and assistance may be called for

CHARLES GODWIN JENNINGS MEMORIAL LECTURE

The FIRST ANNUAL CHARLES GODWIN JENNINGS MEMORIAL LECTURE was held January 27, 1938, under the auspices of the Staff of the Charles Godwin Jennings Hospital Following dinner at the Detroit Club, Dr A F Jennings (Fellow), President of the Board of Trustees and of the Medical Staff, presided at the meeting Brief addresses in memory of Dr C G Jennings (Master, deceased) were given by Dr H R Carstens (Fellow), Mr James Turner, Trustee of the Hospital, and Dr L J Hirschman (F A C S), who introduced the speaker of the evening, Dr Walter C Alvarez (Fellow) of Rochester, Minn Dr Alvarez delivered an address on "Origins of Modern Medicine"

REGIONAL MEETING OF KENTUCKY MEMBERS

About fifty Fellows and Associates of the American College of Physicians resident in Kentucky held their annual meeting and dinner in Louisville under the Governorship of Dr C W Dowden, February 16, 1938 Dr J Murray Kinsman was in charge of arrangements The following program was given at the Louisville City Hospital "The Insulin Treatment of Dementia Praecox," Spafford Ackerly, "The Diagnostic and Therapeutic Uses of the Bronchoscope," Maurice Buckles, "The Gastroscope as a Diagnostic Agent in Diseases of the Stomach," Sam Overstreet, "Demonstration of the Photo-Electric Colorimeter," John Walker Moore, "The Dying Heart," Virgil Simpson

In the evening a dinner meeting was held at the Pendennis Club, at which Dr James H Means, President of the College, was the guest of honor

Dr R A Hare (Fellow), formerly of the Staff of the Santa Barbara Cottage Hospital, Santa Barbara, Calif, has been appointed Medical Director of the Washington Sanitarium and Hospital, Washington, D C

Dr August A Werner (Fellow), St Louis, addressed the Sioux Valley Medical Association, Sioux Falls, S D, January 18, on "Anterior Pituitary-Gonad Relationship in the Female"

Dr Louis F Bishop, Jr (Fellow), New York City, addressed the Rutgers Medical Club January 27 at New Brunswick, N J, on "Coronary Artery Disease"

Dr William D Weis (Fellow), Crown Point, Ind, has been reappointed county health commissioner of Lake County, Indiana, for four years He is the only full-time county health commissioner in that State

Dr J C Geiger (Fellow), Director of Public Health of the City and County of San Francisco, has been granted the decoration, "Cruz de Caballero de la Orden del Merito," by the Government of Chile, for his "good friendship and assistance to that country and for his excellent work in and outstanding contributions to public health"

At a Gastro-Enterologic Symposium held by the Northern Medical Association of Philadelphia (Pa), January 17, Dr Anthony Bassler (Fellow), New York, presented a paper on "Etiology, Symptomatology, and Medical Treatment", Dr Henry A Rafsky (Fellow), New York, on "The Relation of the Anemias and Blood Dyscrasias to Disorders of the Gastrointestinal Tract in Adults" Dr T Grier Miller (Fellow), Philadelphia, was the commentator

Dr Robert M Moore (Fellow), Indianapolis, Ind, was elected President of the Indianapolis Medical Society for the year 1938, at its meeting December 7, 1937

Dr Philip I Nash (Fellow), Brooklyn, has been made President-Elect of the Kings County (N Y) Medical Society

Dr Carl Mundy (Fellow), Toledo, Ohio, has been honored by being elected the President-Elect of the Academy of Medicine of Toledo and Lucas County Dr Mundy will serve as President-Elect for 1938 and will assume the Presidency in 1939 He is also Chairman of the Advisory Board of Health for Toledo, which board counsels with the City Manager and the City Director of Health in matters of local health policy and health administration In addition to these activities, Dr Mundy is Director of Medicine at Lucas County Hospital

At the Thirty-Fourth Annual Congress on Medical Education and Licensure held in Chicago February 14 and 15, the following Fellows of the College participated

Dr Willard C Rappleye, Dean of Columbia University College of Physicians and Surgeons and President of the Advisory Board for Medical Specialties, "The Functions of the Special Examining Boards",

- Dr Burrell O Raulston, Professor of Medicine, University of Southern California School of Medicine, Los Angeles, "An Introduction to Clinical Medicine and Some Variations in the Curriculum of the Third and Fourth Years in Medical School",
- Dr J G FitzGerald, Director of the School of Hygiene and Connaught Laboratories, University of Toronto, "Undergraduate Instruction in Preventive Medicine",
- Dr J H Musser, Professor of Medicine, Tulane University School of Medicine, New Orleans, "Graduate Medical Education for the Internist",
- Dr James D Bruce, Director of the Department of Postgraduate Medicine of the University of Michigan, Ann Arbor, "Continuing Professional Education"
-

Dr Hyman I Goldstein (Associate), Camden, N J, was elected Vice President of the Northern Medical Association of Philadelphia (founded in 1846) for 1938 Dr Goldstein was also elected a corresponding member of the Hungarian Dermatologic Association, Budapest, Hungary, as recently confirmed by the Royal Minister of Internal Affairs of the Hungarian Government

The cornerstone of the new diagnostic clinic at the Boston Dispensary, Boston, Mass, was laid during December and dedicated to Dr Joseph H Pratt (Fellow), Professor of Clinical Medicine at Tufts College Medical School The building is to be known as the Joseph H Pratt Diagnostic Hospital The cornerstone was laid on Dr Pratt's sixty-fifth birthday The building was made possible by recent gifts of William Bingham, 2d, because of his interest in providing a medical center at which the development of rural medicine may be planned and supervised

Dr Anton J Carlson (Fellow), Professor of Physiology in the University of Chicago, is a member of the editorial committee of the "Annual Review of Physiology," in which it is proposed to review developments of each year or biennium in the major fields of physiologic research

A recent announcement by the Advisory Board for Medical Specialties states that a Commission on Graduate Medical Education has been created "to mobilize current opinion as to how the problems in this field can best be solved and to formulate the educational principles involved in graduate medical training" The president of the board, Dr Willard C Rappleye (Fellow), New York City, appointed four members of the board to form the Commission Among members of the Commission are the following Fellows Dr James D Bruce, Ann Arbor, Dr Anton J Carlson, Chicago, Dr Reginald Fitz, Boston, Dr Willard C Rappleye, New York, Dr Harold L Rypins, Albany, Dr Alfred Stengel (Master), Philadelphia, and Dr John B Youmans, Nashville

Dr Waller Smith Leathers (Fellow), Dean of Vanderbilt University School of Medicine, Nashville, Tenn, was selected as the speaker on medical education before a series of educational symposiums, which marked the formal inauguration exercises of Rufus Carrollton Harris, LL D, as the tenth president of Tulane University of Louisiana, New Orleans, during January Dr C C Bass (Fellow), Dean of the medical school at Tulane, presided

A library on tuberculosis, named in honor of the late Dr Luther F Warren (Fellow, deceased), was dedicated recently at a memorial service held for Dr Warren at the Brooklyn Home for Consumptives, of which Dr Warren was the medical director from 1932 until his death during January, 1937. Dr Warren was for a number of years very active in the American College of Physicians, being the Governor of the College for eastern New York and later a member of the Board of Regents and of the Committee on Credentials. He was Professor of Medicine at Long Island College of Medicine and Physician-in-Chief to the Long Island College Hospital.

Dr Asher Yaguda (Fellow), Newark, N J, has been elected President of the newly organized New Jersey Society of Clinical Pathologists.

Dr Fred M Smith (Fellow and Governor of the College for Iowa), Professor of the Theory and Practice of Medicine in the State University of Iowa College of Medicine, Iowa City, has been appointed the new Editor of the *American Heart Journal*, succeeding Dr Lewis A Conner (Fellow), Professor of Clinical Medicine at Cornell University Medical College, New York, who has retired. Among the new associate editors is Dr Irving S Wright (Fellow) of New York City.

Dr Russell S Anderson (Associate), until recently a member of the staff of the Michigan State Sanatorium, Howell, Mich, has been appointed Superintendent of a new hospital for the treatment of tuberculosis in Erie County, near Erie, Pa.

In connection with a three-day ceremony marking the inauguration of Oliver C Carmichael, LL D, as Dean of the Graduate School and Senior College of Vanderbilt University, Nashville, Tenn, the following Fellows participated in the symposium devoted to Medicine:

- Dr William D Cutter (Fellow), Secretary, Council on Medical Education and Hospitals, American Medical Association, "Trends in Premedical and Medical Education",
 - Dr Thomas Parran (Fellow), Surgeon General of the U S Public Health Service, Washington, D C, "A Forward Look at National Health",
 - Dr Wilburt C Davison (Fellow), Dean of Duke University School of Medicine, Durham, N C, "A Survey of Medical Education in the South"
-

Dr Ernest E Irons (Fellow), Clinical Professor of Medicine and formerly Dean, Rush Medical College, Chicago, delivered a public lecture on "The Problem of Arthritis and Its Causes" at the Goodman Theater January 23, under the auspices of the Chicago Medical Society.

Dr Paul A O'Leary (Fellow), Rochester, Minn, has been elected Vice President of the newly formed American Academy of Dermatology and Syphilology. Dr Samuel Ayers, Jr (Fellow), Los Angeles, and Dr Everett S Lain (Fellow), Oklahoma City, were elected to its Board of Directors.

Among the speakers at the fifty-third annual session of the Mid-South Post Graduate Assembly, held at the Hotel Peabody, Memphis, February 15-18, Dr J H Means (Fellow and President), Boston, delivered a paper on "Treatment of Some of the Commoner Medical Emergencies" and Dr Russell L Haden (Fellow), Cleveland, delivered a paper on "Treatment of Anemia"

At the eighth annual conference of the American College of Radiology, held jointly with the Conference of Teachers of Clinical Radiology, at Chicago, February 13, Dr Byrl R Kirklin (Fellow), Associate Professor of Radiology, University of Minnesota (Mayo Foundation), and Secretary of the American Board of Radiology, delivered an address on "The Responsibility of the American Board of Radiology for Setting Up and Maintaining Standards in Radiologic Education" Dr Benjamin H Orndoff (Fellow), of Chicago, presented a paper on "The Bedside Manner in Radiology"

Under the Presidency of Dr Roscoe L Sensenich (Fellow), South Bend, Ind, the annual Northwest Regional Conference was held in Chicago February 13, the general subject of the Conference being "Medical Care for all the People" Dr Herman M Baker (Fellow), Evansville, Ind, addressed the Conference on "Preventive Medical Care as an Activity of County Medical Societies"

Dr Felix J Underwood (Fellow), Jackson, Miss, has been reappointed as executive officer of the Mississippi State Board of Health

Dr Walter Freeman (Fellow), Washington, D C, addressed the Missouri-Kansas Neuropsychiatric Association February 15 on "Experiments in Prefrontal Lobotomy in the Treatment of Mental Disorders"

Dr John Hamilton Crawford (Fellow), Assistant Professor of Pharmacology and Clinical Professor of Medicine, Long Island College of Medicine, Brooklyn, has been appointed Professor of Clinical Medicine and Director of the Long Island College division at Kings County Hospital

On February 9, 1938, Drs Anthony Bassler (Fellow) and Samuel Weiss (Fellow) of New York City, were decorated by the French Government with the Legion of Honor for their contribution to Medicine and Gastro-Enterology

Dr Joseph H Barach (Fellow), Pittsburgh, Pa, and Dr T E Newell, Dayton, Ohio, were the guest speakers at the annual banquet of the Stark County Medical Society at Canton, Ohio on Wednesday, February 9, 1938 The subject was "The Present Status of Medicine in the South American Countries"

Dr Clarence E de la Chapelle (Fellow), Assistant Professor of Medicine at the New York University College of Medicine, is serving as Acting Chairman of the Department of Medicine, pending the filling of the professorship, and as Acting Director of the Third Medical Division at Bellevue Hospital

OBITUARIES

DR SOLOMON LEON CHERRY

Solomon Leon Cherry (Fellow, 1920) died at his home in Clarksburg, W Va, October 21, 1937 of hypertensive heart disease, which first became manifest in January preceding

Dr Cherry was born in Russian Poland, April 10, 1887, and came to America with his parents in 1890. He attended Philadelphia and Baltimore Public Schools and graduated with the M D degree from the University of Maryland Medical School in 1908. He interned in Pathology at Bayview Hospital, Baltimore, 1908-09, and was resident in Pathology, Hebrew Hospital, Baltimore, 1909-10. He was Pathologist, Mt Sinai Hospital, Philadelphia, 1910-13. From 1913-18 he was Pathologist, St Mary's Hospital, Clarksburg, W Va. In 1918-19 he served overseas as a captain in the Army Medical Corps, where he was assigned to Evacuation Hospital No 24 as Chief of the Laboratory Service. After his discharge from the Army in 1919, he returned to Clarksburg as Pathologist, St Mary's Hospital, which position he held until the time of his death. He was Bacteriologist, City of Clarksburg Health Department, past President and Secretary, Harrison County Medical Society, a member of the West Virginia State Medical Association, of the Southern Medical Association, a Fellow of the American Medical Association, a Fellow of the American Society of Clinical Pathologists, a member of the Catholic Hospital Association, and Secretary of the Medical Advisory Board, St Mary's Hospital, Clarksburg.

Dr Cherry was always a student, earnest and hard-working, but rather retiring in disposition. Surviving are his widow and two sons.

WALTER E VEST, M D, F A C P,

Governor for West Virginia

DR GRAYSON EMERY TARKINGTON

Grayson Emery Tarkington, Fellow of the American College of Physicians since 1920, died at Albuquerque, New Mexico, Jan 12, 1938. Dr Tarkington was born at Oakland, La in 1894. He attended Hot Springs high school, Hot Springs, Ark, and graduated from the University of Maryland College of Physicians and Surgeons in 1917. During 1930 he pursued postgraduate work in psychiatry and neurology at the University of Colorado. He was formerly Chairman of the Medical Board, Director of the Out-Patient Department and Visiting Physician to the Leo N Levi Memorial Hospital, Hot Springs, formerly Chief of the Syphilis Staff of the U S Public Health Service Clinic, Hot Springs, also formerly a member of the House Staff of St Joseph's Infirmary, Hot Springs, formerly

President of the Garland County (Ark) Medical Society, formerly First Vice President of the Arkansas State Medical Society, Fellow of the American Medical Association, formerly Secretary of the Hot Springs Board of Health, formerly Associate Editor of the American Journal of Syphilis, member of Nu Sigma Nu Fraternity, served during the World War as First Lieutenant, Medical Reserve Corps, U S Army, author of many published articles. Because of ill health he removed to Albuquerque, N M, during 1933, where he became a member of the Staff of the Children's Home and Hospital, Southwestern Presbyterian Sanatorium and St Joseph's Sanatorium and Hospital.

Dr Tarkington was not merely a physician, he was a citizen. Many demands were made upon his crowded time by welfare, public health and similar activities, and he never failed to respond. As Director of the Out-Patient Department of the Leo N Levi Memorial Hospital he was as attentive to its details as to his private practice and much of the present success of this institution is due to his interest in its organization and functioning. His love of medical study induced him to serve as Associate Editor of the *American Journal of Syphilis* without compensation. In this capacity some two hundred medical journals were received monthly from which many of the articles were abstracted, filed and indexed. Few medical men had better command of current medical literature than he. When in 1933 he moved to Albuquerque, his generous and forceful personality was sadly missed in Hot Springs.

WILLIAM H DEADERICK, M D, F A C P,
Hot Springs, Ark

DR CHARLES EASTMOND

Dr Charles Eastmond (Fellow), of Brooklyn, N Y, died November 27, 1937, in the Peck Memorial Hospital, of carcinoma of the bladder.

Dr Eastmond was born in Brooklyn in 1879, and received his medical education at Columbia University College of Physicians and Surgeons, graduating in 1904. Early in his career he determined to follow the specialty of roentgenology, and proceeded to prepare himself along that line. For many years he was roentgenologist to the Carson C Peck Memorial and the Bushwick Hospitals, and consulting roentgenologist to the Kings County, Long Island College, Jewish, Jamaica and Nassau (Mineola) Hospitals and the Norwegian Lutheran Deaconesses' Home and Hospital. He contributed many papers dealing with roentgenology to medical journals, and was active in many medical societies. He was a member of the Medical Society of the County of Kings, the Medical Society of the State of New York, the Brooklyn Medical Association, the Brooklyn Pathological Society, the Medical Association of Greater New York, the Medical Club of Brooklyn, the Hospital Graduates Club of Brooklyn, Practitioner's Club of Brook-

lyn, the Associated Physicians of Long Island, the American Medical Association, the New York Roentgen Society, the American Roentgen-Ray Society, and had been a Fellow of the American College of Physicians since 1920

DR CHARLES D VER NOOY

Dr Charles D Ver Nooy, of Cortland, N Y, Associate of the College since March 10, 1923, died January 20, 1938, following a heart attack suffered the night preceding. He had been in poor health for the past year.

Dr Ver Nooy was born in Accord, Ulster County, New York, February 16, 1868, a descendant of early settlers there. His education was received in the public schools of Ulster County and the Cortland Normal School. For four years he taught school, after which he studied medicine at Syracuse University, graduating in 1892. He opened an office in Enfield, N Y, but later removed to Cortland in 1898. He early established a reputation for his diagnostic ability and keen observation in the medical field. In his early days his calls were made with horse and buggy. In 1912 he took over the old Cortland Hospital, remodeled it into the Ver Nooy Sanitarium and conducted it as a small hospital and as his private office.

Dr Ver Nooy was a member of the Cortland County Medical Society, the Medical Society of the State of New York and the American Medical Association. He became an Associate of the American College of Physicians in 1923. Outside of his medical work, he had been a pioneer in the extension of the telephone in his community, having been a Director and President of the old Cortland Telephone Company before its merger with the present system. Dr Ver Nooy had been a member of the local Board of Education since 1917, and for twenty years had acted as its President. He was a charter member of the City Board of Health, a Director of the Marine Midland Trust Company and Chief of the Staff at the Cortland County Hospital.

C F TENNEY, M D, F A C P,
Governor for Eastern New York

DR LORENA M BREED

Dr Lorena M Breed (Fellow), Pasadena, California, died October 20, 1937. She had been retired from medical practice for some time. Dr Breed was born at Washington, Iowa, in 1863, received her pre-medical training at the Central University of Iowa and graduated from the Northwestern University Woman's Medical School in 1893. She was early interested in clinical laboratory work. At one time she was connected with the Nalgonda Hospital in India, later returning to California. From 1895 to 1906 she again was in India, and connected with the Hyderabad State Deccan. From 1908 to 1914 she was in charge of the clinical laboratory

of the Pomona (Calif) Valley Hospital and from 1914, for several years, she was in charge of the clinical laboratory of the Pasadena (Calif) Hospital

Dr Breed was the author of several published articles and of a book entitled " The Human Machine, Its Uses and Abuses " She was a member of the Los Angeles County Medical Society, the California State Medical Society, the American Medical Association and the American Society of Bacteriologists She became a Fellow of the American College of Physicians on December 30, 1921

THE CRUCIAL TEST—Laboratory tests are not always decisive. Clinical trial is essential really to prove the merit of new drugs. The Lilly trade-mark on pharmaceuticals and biologicals is assurance of conscientious testing both in the clinic and in the laboratory.

'Extralin' (Liver-Stomach Concentrate, Lilly) is typically a product of Lilly Laboratory research. It simplifies and improves the oral treatment of pernicious anemia. The bulk of a dose of 'Extralin' is small and the capsules are tasteless. 'Extralin' is supplied in bottles of 84 and 500 pulvules (filled capsules).

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts, Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physicians. The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College.

MANUSCRIPTS All correspondence relating to the publication of papers and all books and monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following style:

4 DOE, J. E. What I know about it, Jr. Am Med Assoc, 1931, xcvi, 2006-2008

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations.

REPRINTS For each article published, there will be furnished gratis fifty reprints without covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are wanted the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and books bearing upon the field of internal medicine. Authors and publishers wishing to submit such material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made in the department of reviews.

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid: \$7.00, United States, Canada, Mexico, Cuba, Canal Zone, Hawaii, Porto Rico, \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. Members of the American College of Physicians receive the ANNALS OF INTERNAL MEDICINE as a part of their membership. Checks should be drawn to the order of W. D. STROUD, M.D., Treasurer, and remitted through the Publication Office or the Executive Secretary's Office.

BUSINESS CORRESPONDENCE. All correspondence relating to business matters, advertising, subscriptions to the ANNALS, inquiries concerning membership in the American College of Physicians, et cetera, should be addressed to the Publication Office or to the Executive Secretary. Books and reprints presented to the College Library should be addressed to the Executive Secretary.

is the Shortest Distance . .

The "Hindle" Electrocardiograph employs as its sensitive element the Einthoven String Galvanometer . . . the fundamental means of directly recording the minute heart currents without external amplification. Proof of the basic soundness of this direct method is that it has stood the test of time. From the day of the introduction of the "Hindle", nearly a quarter of a century ago, it has been the very symbol of accuracy and dependability. No detours . . it has followed the straight line

The new Hindle All Electric models are made in stationary, mobile and portable types for hospitals, clinics and private offices.

Two million sufferers . . . 80 per cent.
will be benefited by proper

HAY FEVER TREATMENT

THE INCIDENCE OF HAY FEVER has been variously estimated as between 1 and 2 per cent of the population of the United States. Some recent estimates are even higher. Thus there are about two million hay fever sufferers in this country.

Clinical reports indicate that at least 80 per cent of the cases will obtain satisfactory relief following properly managed pollen therapy.

With the development of Lederle's glycerolated pollen extracts, the testing and treatment of pollen sensitiveness have been simplified and improved.

A single diagnostic scratch test usually suffices to classify the patients according to their constitutional sensitivity, and to indicate the size of the dosage.

"Pollen Antigens Lederle" have shown no measurable deterioration after six years. Physicians will therefore find it advantageous to keep on hand a supply of diagnostic tests (each package contains sufficient material to test 3 individual cases). The scratch test may be performed at any season and treatment by the preferred perennial method commenced at any time.

HAY FEVER

Diagnostic Scratch Tests to

(C) Determine Pollen and Dosage

($\frac{3}{8}$ " or less across)
A weak reaction which occurs in over 10 per cent of all hay-fever subjects. Probable dosage, 60 units to 6,000 units or more.

(B)

($\frac{1}{2}$ " to $\frac{3}{4}$ " across)
An "average" reaction, occurring in about 80 per cent of all hay-fever subjects. Probable dosage, $2\frac{1}{2}$ to 3,000 units.

(A)

(1" or more across)
A very marked reaction, occurring in about 5 per cent of all hay-fever subjects. Probable dosage range between 1 unit and 450 units.

Reducing the risk
of severe serum reactions in

SCARLET FEVER ANTITOXIN THERAPY

TIME WAS WHEN PHYSICIANS confronted with a case of scarlet fever felt themselves in a dilemma. The use of antitoxin meant a serious risk of serum reactions, withholding it left the patient in danger.

Antitoxin was, therefore, frequently given only in severe cases, with the result that many of the milder cases progressed to the severe form of the disease, with a lower expectancy of effectiveness of serum therapy when instituted late.

The advent of Globulin Modified Scarlet Fever Streptococcus Antitoxin *Lederle* has changed the old attitude towards antitoxin therapy. This potent antitoxin with its greatly reduced liability to cause reactions is now being widely used regardless of apparent mildness of attack. The decrease in the incidence of serious complications alone, aside from the favorable effect on the prognosis, far over-balances the lingering hazards involved in the 2% incidence of severe serum reactions following the use of this antitoxin.

"Scarlet Fever Streptococcus Antitoxin (Globulin Modified) *Lederle* is available in appropriate packages for both prophylaxis and therapy.

KEEP *Heart Disease* IN MIND

● A wise physician has said—"Of importance comparable to the DIAGNOSIS of cardiac disease is the RECOGNITION of its ABSENCE"

Your patients will appreciate your having a FULL knowledge of the condition of their hearts. There are few among them who would not welcome your suggestion that a THOROUGH investigation be made, including an electrocardiographic examination.

You can do this now because the extremely accurate, thoroughly dependable, light-weight, low-priced, G-E electrocardiograph has brought this valuable diagnostic medium within the reach of every physician. With the possibility of heart disease in mind, you can add electrocardiography *that is accurate* to the other diagnostic equipment and routine that you now employ—and get the COMPLETE picture. So often would you use the electrocardiograph that your investment in it would be liquidated quickly.

See this entirely new and different precision instrument that you can use in your office or at the bedside. Make a cardiogram on it, yourself. Sign and mail the convenient coupon at once without involving any obligation.

DIET

When the impulse to defecate is lessened due to improper diet or lack of discipline, the fecal matter usually becomes dehydrated and impacted in the bowel.

To simplify the problem of bowel regularity, Petrolagar may be prescribed to advantage, as it assists in the regulation of bowel movement. Petrolagar mixes intimately with the bulk of the stool to induce a soft, easily passed mass. By reason of its pleasant taste and mild but thorough action, Petrolagar is agreeable to patients of all ages. Five types of Petrolagar provide a choice of laxative medication suitable for the individual patient. Petrolagar Laboratories, Inc., 8134 McCormick Boulevard, Chicago, Illinois.

KNOX CLINICAL NOTES

ONE OF A SERIES OF CORRESPONDENCE EXCHANGES WITH PHYSICIANS ABOUT KNOX GELATINE.

Query about Knox Gelatine as a Dietary Adjuvant

A friendly doctor writes, "I am treating a case of celiac disease to whom I wish to give gelatine with fruit juices, omitting sugar. I shall appreciate any suggestions you can give me as to its preparation."

Knox Gelatine Laboratory Replies—

Here are two good ways to administer
Knox Gelatine in concentrated form

THE KNOX BANANA STIR

Thoroughly crush one ripe banana. Sprinkle over it 2 envelopes of Knox Gelatine, mixing banana and gelatine while stirring. After it is well mixed, serve.

Total Approximately 250 calories

THE KNOX FRUIT STIR

Place the contents of 2 envelopes of Knox Gelatine in an ordinary saucer or cereal dish. Add 8 tablespoonfuls of any desired fresh or canned fruit juice, such as grape juice. Let soak for five minutes and eat with teaspoon.

Total 4 ounce mixture—100 calories

Why You Should Insist on Knox Sparkling Gelatine

Because Knox Gelatine is 85% protein in an easily digestible form—because it contains absolutely no sugar or other substances to cause gas or fermentation, Knox Gelatine should not be confused with factory flavored, sugar laden dessert powders. Knox is 100% pure U S P gelatine. Knox Gelatine has been successfully used in the dietary of convalescents, anorexic, tubercular, diabetic, colitic, and aged patients.

Sample and useful Dietary Booklets on request Write Dept 476

KNOX SPARKLING GELATINE

IS PURE GELATINE—NO SUGAR

KNOX GELATINE LABORATORIES, Johnstown, N.Y.

The *SEDATIVE* with a wide range
of *THERAPEUTIC*
USEFULNESS

THE value of Luminal and Luminal Sodium as sedatives and antispasmodics is universally recognized. Few drugs in the modern materia medica have been the subject of such a voluminous literature. This is not surprising in view of the remarkable action of Luminal and Luminal Sodium in epilepsy and their established efficacy in other convulsive disorders. As might be expected the field of indications has been extended to the milder manifestations of nervous excitability such as are frequently encountered in various diseases both of functional and organic character.

Among the conditions in which Luminal Sodium is more particularly applicable are status epilepticus, eclampsia, tetanus, vomiting of pregnancy and cocaine and other poisoning.

The dose should not exceed 10 grains in twenty-four hours. The effect of such large doses should be closely watched.

HOW SUPPLIED Luminal and Luminal Sodium tablets of ¼ and ½ grain, bottles of 100 tablets of 1½ grains, bottles of 50. Also Elixir of Luminal (¼ grain to teaspoonful), bottles of 4 oz. and 12 oz. Luminal Sodium ampules (2 grains and 5 grains), boxes of 5, 25 and 100.

Philadelphia, Pa.

Urinary excretion of bismuth after multiple injections of Iodobismitol. Arrows indicate injections.

IN A RECENT CLINICAL STUDY,¹ patients were given 2-cc doses of Iodobismitol twice weekly for a period of three weeks. The charts illustrated above show the urinary excretion of bismuth over a period of four weeks—49% of the bismuth having been excreted. This would serve to "indicate that Iodobismitol is capable of developing a potent bismuth level in the blood stream."

This effect seems highly desirable for, according to the Council on Pharmacy and Chemistry, "Probably those compounds of bismuth will have the best antispirocheticidal value that are able to keep the therapeutic level of bismuth in the blood stream at such a continuous height that it will be re-

flected in the urine with a level of 0.003 Gm or more of metallic bismuth per day."

Iodobismitol may be used alone or with the arsenicals. It is well tolerated in both early and late syphilis. Iodobismitol is almost completely absorbed, exerts a relatively prolonged effect at a high level, and a very high efficiency with respect to therapeutic utilization of the dosage given.

Iodobismitol with Saligenin is a propylene glycol solution containing 6% sodium iodobismuthite, 12% sodium iodide, and 4% saligenin (a local anesthetic). It presents bismuth largely in anionic (electro-negative) form.

For bland diet therapy, especially ULCER cases — PABLUM

FAR too often the bland diet prescribed for gastric ulcer, colitis, and similar gastro-intestinal disorders is a deficient diet. An analysis made by Troutt of ulcer diets used by 6 leading hospitals in different sections of the country showed them to be "well below the Sherman standard of 15 milligrams" in iron and low in the water-soluble vitamins.¹ "Vitamin B would appear to be represented at a maintenance level in most cases," writes Troutt, "but the possible relation of vitamin B to gastro-intestinal function and appetite should make one pause before accepting a low standard."

Low in Fiber — High in Iron

Pablum is the only food rich in a wide variety of the accessory food factors that can be fed over long periods of time without danger of gastro-intestinal irritation. Its fiber content is only 0.9%. Yet Pablum contains 37 times more iron than farina and is an excellent source (+ + +) of vitamins B and G, in which farina is deficient. Supplying $8\frac{1}{2}$ mgms. iron per ounce, Pablum is 8 times richer than spinach in iron.

Rich in Vitamin B

The high vitamin B content of Pablum assumes new importance in light of recent laboratory studies showing that avitaminosis B predisposes to certain gastro-intestinal disorders. Apropos of this, Cowgill says, "Gastric ulcer is another disorder which can conceivably be related to vitamin B deficiency. Insofar as the treatment of this condition usually involves a marked restriction of diet the occurrence of at least a moderate shortage of this vitamin is by no means unlikely. Obviously the length of the period of dietary restriction is an important determining factor. Dalldorf and Kellogg (1931) observed in rats subsisting on carefully controlled diets that the incidence of gastric ulcer was greatly increased in vitamin B deficiency. Observations of this type merit serious consideration."²

Requiring no further cooking, Pablum is especially valuable during the healing stage of ulcer when the patient is back at work but still requires frequent meals. Pablum can be prepared quickly and conveniently at the office or shop simply by adding milk or cream and salt and sugar to taste. Pablum has the added advantage that it can be prepared in many varied ways—in muffins, mush, puddings, junket, etc. Further, Pablum is so thoroughly cooked that its cereal-starch has been shown to be more quickly digested than that of farina, oatmeal, cornmeal, or whole wheat cooked four hours in a double boiler (studies in vitro by Ross and Burrill).

In addition to all the above points Pablum has the advantage of being the only base-forming cereal (except Mead's Cereal which is the uncooked form of Pablum).

Pablum consists of wheatmeal, oatmeal, cornmeal, wheat embryo, alfalfa, yeast, beef bone, reduced iron and sodium chloride.

NUMBER 10

GRAVE SEQUELAE OF BLOOD TRANSFUSIONS, A CLINICAL STUDY OF 13 CASES OCCURRING IN 3500 BLOOD TRANSFUSIONS

By ELMER L. DEGOWIN, M D, *Iowa City, Iowa*

By the year 1910, the contributions to our knowledge of isohemagglutination made by Landsteiner, Shattock, Hektoen, Jansky, Moss, and others had laid the foundation for a great reduction in mortality from the transfusion of blood. The introduction of citrated blood by Agote, Weil, and Lewisohn during the World War, provided a much simpler method than had been in previous use. As a result of the reduction in hazards and the increase in technical facility, blood transfusion has become a common therapeutic procedure. The ease of administration and the relatively small mortality have unfortunately impressed many operators only with the innocuousness of the treatment. Despite the warnings of many writers, it must be true that serious complications have frequently occurred but have not received proper notice in the medical literature. A survey of recent publications on blood transfusion reactions indicates that interest in the subject is being reawakened.

The reactions following blood transfusion have been variously classified. Polayes and Lederer¹ have published an excellent review of the subject. Because of the lack of knowledge of the exact mechanisms involved, any etiological classification at present must necessarily contain potential errors. In this paper the various allergic manifestations, febrile reactions, and the transmission of disease will be ignored. The serious reactions which result in jeopardy of life or in permanent damage will be considered and illustrated with appropriate cases from our experience.

From November 1933 to July 1937, approximately 3,500 blood transfusions were performed in the University Hospitals of the State University of Iowa. Citrated blood was utilized almost exclusively. It was administered through small needles by gravity. All serious complications result-

From the Department of Internal Medicine, State University of Iowa Medical College, Iowa City.

ing from transfusion were studied as thoroughly as circumstances permitted. All transfusions were administered by the interns under supervision of the resident staff. No "transfusion teams" were utilized. The hospital maintained a donor list consisting mostly of the resident staff, interns, nurses, employes, and medical students. Beginning July 1, 1936, a physician in the bacteriology laboratory was made responsible for the determination of the blood groups of all donors and recipients except in the case of some emergencies. The interns performed the cross-matching of donors' and recipients' bloods under supervision. Most of the transfusions were given with bloods of the same group although bloods of Group O were occasionally used when the homologous group was not available.

RENAL INSUFFICIENCY FROM BLOOD TRANSFUSION

The syndrome of uremia with oliguria or anuria has long been known to occur, not only in hemolytic transfusion reactions but also in blackwater fever and in hemoglobinemia caused by various drugs such as quinine² and phenylhydrazine. The mechanism has been variously explained. Bordley³ discussed four theories which had been proposed. 1. Baker and Dodds⁴ suggested that the renal tubules become blocked by hemoglobin pigment precipitating in an acid solution. They produced the condition in rabbits and this work has been recently confirmed experimentally in dogs by DeGowin, Osterhagen, and Andeisch.⁵ The principal objection to this theory is that in many human cases not enough pathologic evidence of tubular obstruction can be found. 2. The renal lesions are the result of loss of chlorides similar to the cases described by Brown et al.⁶ Chemical study of many cases does not justify this explanation. 3. Longcope and Rackemann⁷ described cases with urticaria which developed renal insufficiency. It has been suggested that this mechanism might be involved in transfusion anuria. This is difficult to disprove save that the clinical syndrome can be reproduced in dogs with a single transfusion.⁵ 4. A nephrotoxic substance is released by hemolysis. This has no experimental proof at present. A fifth explanation has been introduced by the work of Mason and Mann⁸ and Hesse and Filatov⁹ which demonstrated a vasoconstrictor action of hemoglobin on the kidney. Hesse and Filatov believe that the renal damage is due to ischemia. The experimental work of the latter workers requires confirmation.

Most writers have agreed that the renal insufficiency following blood transfusion is dependent on hemolysis resulting from the administration of incompatible blood. Whether there is an alternative explanation in some cases remains to be proved. Cases of transfusion anuria have been reported where no incompatibility of bloods could be demonstrated by the usual laboratory methods and in which hemoglobinuria was not noted.^{10, 11, 12} Failure to demonstrate incompatibility in these cases can scarcely be ascribed to faulty technic as all of these tests were checked subsequent to the transfusion reactions, a situation which naturally constituted a stimulus to careful

work. A more plausible interpretation is that for a small number of bloods our present laboratory methods are inadequate to detect all incompatibilities. The absence of hemoglobinuria and jaundice does not constitute unequivocal evidence that hemolysis did not occur. Lichty, Havill, and Whipple¹³ have shown that there is a renal threshold for hemoglobin, and Drabkin, Widerman, and Landow¹⁴ have calculated that only about 10 per cent of the hemoglobin disappearing from the blood plasma is excreted in the urine. Two of our cases had hemoglobinemia two hours after transfusion reactions but in neither could hemoglobin be detected in the urine.

Undoubtedly the most common cause of the transfusion of incompatible blood is still the occurrence of gross errors in the preliminary cross-matching. It is difficult to conceive of any laboratory procedure in which an error can directly cause more disastrous results to the patient than in blood matching and blood grouping. Yet conversation with many interns graduated from various recognized medical schools reveals that they have only a very rudimentary and fragmentary knowledge of all procedures pertaining to the determination of blood incompatibility, transfusion technic, and transfusion reactions. In fact, a survey of the standard textbooks on laboratory diagnosis demonstrates that many of the presentations of the subject are inadequate reflections of our present knowledge. It has become necessary in this hospital to give lectures and laboratory demonstrations to each new class of interns.

CASE REPORTS

*Case 1*¹⁵ E. A., a 53 year old woman, had hemorrhages from the colon, probably as a result of roentgen irradiation for adenocarcinoma of the cervix uteri. Her blood was classified as Group O. In October 1931, she received transfusions from two Group O donors without reaction. In October and November 1933, three transfusions were given from different Group O donors with a febrile reaction following each. Preliminary cross-matchings by the hanging-drop method revealed no incompatibilities. The last transfusion was made with washed erythrocytes only. Immediately after transfusion she complained of severe pain in the neck, thighs, and abdomen. This was followed by a chill and the temperature rose to 103.2° F per rectum. Jaundice was evident within seven hours. The urine was diminished in volume and contained hemoglobin and granular pigment casts. The patient continued to vomit, she became drowsy and generalized edema developed. Death in coma occurred ten days after the transfusion. Permission for autopsy was refused. After the reaction had occurred the donor's and the recipient's bloods were re-typed and cross-matched. They were found to belong to Group O and no agglutination could be observed. There was some hemolysis of the donor's corpuscles by the recipient's serum, however. It is possible that more suitable laboratory methods might have demonstrated the incompatibility more satisfactorily.

Treatment. Intravenous injections of isotonic saline and hypertonic dextrose solutions, diathermy to the kidney regions, irrigation of the renal pelves with hot water, phlebotomy with withdrawal of 200 c.c. of blood.

Blood chemical studies shown in table on top of page 1780.

*Case 2*¹⁵ W. B., a 65 year old man, had bleeding from a duodenal ulcer. His blood was classified as Group O. During November 1933 he received two transfusions from donors who were supposed to belong to Group O. Preliminary cross-

matching by the hanging-drop method revealed no incompatibilities. There was no reaction after the first transfusion. During the second transfusion, after 75 cc of blood had been given, the patient complained of a cramp in the thigh. A total of 500 cc of blood was given. One hour afterward he became nauseated and vomited, a slight chill was followed by a temperature of 100.4° F per rectum. Complete anuria developed. No jaundice was detected but examination of the blood plasma was not made until two days after transfusion. The patient continued to vomit, gradually become stuporous and died in coma 10 days after transfusion. Cross-matching of the recipient's blood with that of the last donor by the hanging-drop method revealed no incompatibility. Three years later, the donor's blood was typed with sera of high titer and found to belong to Group A. The donor stated that he had given eight transfusions as a Group O without reactions.

Treatment Isotonic saline intravenously and by hypodermoclysis, hypertonic dextrose intravenously, irrigation of the renal pelvis with hot water.

Autopsy The pathologist reported the significant lesions to be central necrosis of the liver lobules and necrosis of the tubular epithelium of the kidneys with some plugging of the lumina with debris and pigment.

Case 3 A Z, a 57 year old man, was admitted to the hospital November 28, 1934, in semi-coma. He had been known to have pernicious anemia for four years.

He was pale, disoriented, and afebrile. Extensive retinal hemorrhages were present. The blood pressure was systolic 125 and diastolic 75 mm of mercury. The urine contained some albumin, erythrocytes, and a few coarse casts composed of brownish pigment. Hemoglobin 38 per cent (Sahli), erythrocytes 1,650,000 and leukocytes 23,450 per cu mm, reticulocytes 17 per cent. The patient vomited frequently and developed edema of the ankles. The urinary volume for three days was 850 c c. He died in coma three days after admission.

| November 30 | 155.4 | 18.5 | 12.3 | 25.8 | 587 | 0.8 direct |

Treatment. Isotonic saline and hypertonic dextrose solutions intravenously.

Autopsy. The following anatomic diagnoses were made: hyperplasia of the bone marrow, hemosiderosis of the liver and spleen, slight chronic gastritis, degeneration of the posterior columns of the spinal cord, acute tubular nephritis (blood transfusion reaction), acute cholecystitis, acute myocarditis, passive congestion of the lungs, bilateral pleural effusion, old hemorrhages of cerebellum, polyp of sigmoid colon, emphysematous cystitis.

The pathologist was the first to suggest that the patient had died from a blood transfusion reaction. Subsequent correspondence with the referring physician revealed that on November 20 the patient had received 300 c c of whole blood from a type O donor. This was immediately followed by a severe chill and an oral temperature of 100.8° F. On November 23 he had received another transfusion of 250 c c of blood which was followed by a chill. Death, then, occurred 10 days after the first transfusion.

Case 4. A. P., a 57 year old man, was admitted to the hospital December 31, 1934, with severe bilateral pyelonephritis, chronic cystitis, benign hyperplasia of the prostate, and bilateral ureteritis. An indwelling urethral catheter was placed and he was given ammonium nitrate, 14 grams (gr 22½) thrice daily, and serenum, five grains thrice daily. His blood was classified as Group O and was apparently compatible with that of the donor whose blood produced the fatal reaction in Case 2. On January 8, 250 c c of this donor's blood had been given to the recipient when the transfusion was discontinued because the patient developed a severe chill and oral temperature of 105.2° F. Anuria promptly developed. Vomiting and stupor intervened. On January 12 the condition was desperate. There was some edema of the lungs. In spite of that, it was thought that some risk should be taken in an effort to start urinary excretion. Thirty milligrams acetyl β methylcholine were given intravenously. The patient suddenly became much more dyspneic, apparently from increasing pulmonary edema. Atropine sulphate 0.13 mg (gr 1/50) was given intravenously with some relief of dyspnea for about two hours but then the extreme dyspnea recurred and the patient died (four days after transfusion).

The bloods of recipient and donor were again cross-matched by the hanging-drop method and no incompatibility was noted. As was reported in Case 2, the donor was proved three years later to belong to Group A when sera of high titer were used.

Treatment. Isotonic saline and hypertonic dextrose solutions intravenously,

roentgen irradiation of the kidney regions, acetyl β methylcholine Autopsy revealed advanced pyelonephritis

| January 12 | 105.7 | 11.4 Death |

Case 5 E. S., a 50 year old woman, was admitted to the hospital with chronic glomerular nephritis. She was pale and slightly edematous. The retinæ were normal except for arteriosclerosis. The area of cardiac dullness was somewhat enlarged. Blood pressure systolic 170 and diastolic 100 mm of mercury. There was gross hematuria and moderate albuminuria. Hemoglobin 30 per cent (Sahli), erythrocytes 2,020,000, and leukocytes 8,400 per cu mm. The patient's blood was classified as Group A. On May 2, 1935, she was given 500 cc of citrated blood from a Group A donor without reaction. On May 6, another Group A donor gave her 500 cc citrated blood after preliminary cross-matching. During the administration of the last 50 cc she complained of some abdominal pain. Fifteen minutes later she had a chill and the rectal temperature was 104° F. The next day slight jaundice was noted. The urinary excretion became diminished and the hematuria continued until May 15 when the blood completely disappeared from the urine for the first time during hospitalization. There had been some vomiting since admission but on May 18 this became worse and she became comatose and dyspneic. Peripheral edema developed and the ophthalmologists noted papilledema and retinal hemorrhages. She died May 22, sixteen days after the transfusion.

The donor's and recipient's bloods were retyped and both were found to belong to Group A. However, the recipient's serum agglutinated and hemolyzed the donor's corpuscles as well as the corpuscles of an undoubted Group O. These reactions were evident both by the hanging-drop method and by the macroscopic method using small test tubes.

Treatment Hypertonic saline and dextrose intravenously, sodium bicarbonate intravenously, caffeine citrate intramuscularly, salyrgan intravenously.

Blood chemical studies shown in table on top of page 1783.

Autopsy Permission was granted only for examination of the kidneys. These showed a typical picture of an actively progressive diffuse nephritis with hemosiderosis of some of the tubular epithelium.

Case 6 A. E., a woman, 46 years old, entered the hospital with vaginal hemorrhage from a uterine fibroid. Hemoglobin 50 per cent (Sahli), erythrocytes 2,000,000 and leukocytes 11,000 per cu mm. Her blood was classified as Group A and, after preliminary cross-matching, she was given 500 cc of citrated blood from a Group A donor (Dr. H.) on July 7, 1936. A half hour later she had chills and the oral temperature rose to 104.2° F. There was considerable vomiting and an increase in amount of vaginal hemorrhage. On July 8 she received 550 cc citrated blood from her husband (Mr. E.) whose blood was typed as Group A and seemed compatible by cross-matching. The blood was given at 10 a.m. and was followed by some vomiting but no fever. In the late afternoon jaundice and oliguria were noted. The significance of the oliguria was difficult to evaluate because of the excessive out-

| | | Died | | | | |

side temperature at the time. On July 11 the urinary excretion increased and, subjectively, the patient was better. She received another transfusion from a Group A donor July 12. This was followed by a chill and oral temperature of 103° F. There were no subsequent symptoms, however. On July 22, she received another transfusion from a sister (Group A) with no reaction. On July 27 a transfusion from another Group A donor (Dr. S.) was well tolerated. Vaginal myomectomy was performed July 27 and the patient made an uneventful recovery.

The bloods concerned in the reaction resulting in renal insufficiency were the patient's and those of the donors, Dr. H. and Mr. E. All of these bloods were retyped with sera of high titer and found to belong to Group A. The serum and corpuscles of each were cross-matched with all the others using the hanging-drop, the Vincent open slide method, and the Landsteiner centrifuge method. By none of these tests was any incompatibility ever shown. The possibility that distilled water instead of isotonic saline was added to the blood before transfusion was considered but could not be investigated directly. The stock solutions were tested and no errors in labelling were found.

Blood chemical studies shown in table on top of page 1784.

Treatment. Isotonic saline and hypertonic dextrose intravenously, blood transfusion, spinal anesthesia with procaine hydrochloride. Which of the first two transfusions produced the renal insufficiency is not known. The diuresis and fall in blood urea nitrogen were not prompt enough to be attributed to either transfusion or to the spinal anesthesia. It is the opinion of the clinicians in charge of the case that recovery was spontaneous.

Case 7. D. B., a 28 year old man, had a spastic torticollis following trauma to the head. His blood was classified as Group O. On June 17, 1936, an exploratory craniotomy was performed under avertin anesthesia. During the operation, shock developed and 450 cc citrated blood of Group O were administered in the operating room. Chills developed after he was returned to the ward. Another transfusion

was given in the late afternoon and was followed by chills and rectal temperature of 105.8° F. The patient was unable to void. During the next three days he vomited and hiccoughed considerably. Another transfusion was given with Group O blood on June 19. The bloods seemed to be compatible on cross-matching. On June 20 he was still anuric and another transfusion was given. There was a sudden circulatory collapse which temporarily improved after the administration of epinephrine. The patient died three hours after the last transfusion (three days after operation). Just before death, a blood specimen showed the following: blood urea nitrogen 119.0 mg per cent, blood uric acid 8.0 mg per cent, blood creatinine 8.7 mg per cent, CO₂ combining power 23 vol per cent, plasma chlorides 600 mg per cent. Treatment. As the anuria was not recognized during life, no specific treatment was given. It seems probable, however, that the patient received some compatible blood after the reaction had occurred.

Autopsy. Anatomic diagnoses: Recent left partial cerebro-frontal lobectomy, intracranial hemorrhage, intraventricular hemorrhage, fatty metamorphosis of the liver with central degeneration, lobular pneumonia and edema of the lungs, acute gastric erosions, mild tubular nephritis (some hemoglobin pigment casts present).

The pathologist first made the diagnosis of transfusion anuria.

The treatment of renal insufficiency following blood transfusion reactions has been extensively discussed in the literature. The clinical course is such that the condition could be recognized in time to apply specific treatment were any known. Many procedures have been proposed and have been reported as successful in isolated cases: intravenous fluids both isotonic and hypertonic, diathermy and roentgen irradiation of the kidney regions, irrigation of the renal pelvis with hot water, phlebotomy¹⁶, intravenous sodium bicarbonate, spinal anesthesia¹⁷, decapsulation of the kidneys¹⁸, and transfusions of compatible blood¹⁹. It is notable, however, that some cases recover spontaneously while others die in spite of the therapeutic measures advocated.

Whether alkalinization of the urine prior to the transfusion will protect the kidneys from the excreted hemoglobin, if hemolysis occurs, is very difficult to prove statistically, because of the small incidence of such hemolytic reactions in any series. Baker and Dodds⁴ have shown that such a procedure protects rabbits, and DeGowin, Osterhagen, and Andersch⁵ have shown the same for dogs. It must be emphasized, however, that there are certain chemical differences between the blood of most animals and human blood which may complicate the application of this work to clinical practice. In the present state of our knowledge, however, alkalinization of the urine of the recipient before transfusion would seem a desirable precaution.

Tabulation of the treatment received in our seven cases developing renal insufficiency from transfusion reactions would seem to leave much to be desired in therapeutic efficacy. In none of these cases was decapsulation of the kidneys attempted.

Treatment of Transfusion Anuria

| Treatment | Case Numbers | | | | | | |
|-------------------------------------|--------------|-------|-------|-------|-------|----------|-------|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| Isotonic saline intravenously | \ | \ | \ | \ | \ | \ | \ |
| Hypertonic dextrose intravenously | \ | \ | \ | \ | \ | \ | \ |
| Sodium bicarbonate intravenously | | | | | \ | | |
| Diathermy to the kidney regions | \ | | | \ | | | |
| Roentgen irradiation of the kidneys | \ | \ | | | | | |
| Irrigation of the renal pelves | \ | | | | | | |
| Spinal anesthesia | | | | | | \ | |
| Phlebotomy | \ | | | | | | |
| Acetyl β methvlcholine | | | | \ | | | |
| Caffeine citrate intramuscularly | | | | | \ | | |
| Salyrgan intravenously | | | | | \ | | |
| Blood transfusion | | | | | | \ | \ |

| Termination | Death | Death | Death | Death | Death | Recovery | Death |

HEMOLYTIC REACTIONS WITHOUT RENAL INSUFFICIENCY

It is well recognized that all cases showing hemolysis from blood transfusions do not develop renal insufficiency. Under certain conditions which are not understood, the liberated hemoglobin is taken up by the tissues and a small amount is excreted through the kidneys without apparent harm.

CASE REPORTS

*Case 8*²⁰ E. H., a 25 year old woman, developed postpartum fever. Her blood was classified as Group AB. Because of the lack of donors of homologous group

she received blood from a donor of Group O. Preliminary cross-matching gave the expected result, i.e., the donor's serum agglutinated and hemolyzed the corpuscles of the recipient but the recipient's serum had no effect on the donor's cells. When 125 c.c. of citrated blood had been administered the patient complained of a feeling of constriction in the chest. The transfusion was promptly discontinued but extreme dyspnea and cyanosis ensued. There was a severe chill and the oral temperature rose to 106.2° F. Two hours later the patient's serum was tinged with hemoglobin and the van den Bergh reaction was 2.0 biphasic. No hemoglobin appeared in the urine and 36 hours later the van den Bergh was 0.5 indirect. The symptoms lasted only a few hours and the puerperal infection resolved by crisis. Examination of the donor's serum demonstrated an α hemolysin active in a titer of 1:12 to 1:20 and a corresponding agglutinin active in a dilution of 1:80. The β agglutinin was titered at 1:12.

Case 9 P. S., a 16 months old girl, with athrepsia and nutritional anemia was classified as blood Group AB, and received 150 c.c. of Group AB blood after preliminary cross-matching had shown no incompatibility. Three and one-half hours later the rectal temperature rose to 104.5° F and the pulse was 140 per minute. Hemoglobin was found in the urine. The bloods were retyped and again both classified as Group AB. The recipient's serum, however, was found to agglutinate the donor's corpuscles. The same serum was tested against the corpuscles of several bloods of Groups A and B. It agglutinated most Group B cells but not those of Group A. Two weeks later another transfusion of 150 c.c. of another Group AB blood was given. The rectal temperature rose to 102° F but no hemoglobinuria was noted. The patient made an uneventful recovery.

Case 10 K. A., a 26 year old woman, had pyelitis of pregnancy with intermittent fever. Her blood was classified as Group B. On May 28, 1936 she received 500 c.c. of citrated blood from a Group B donor. This was followed by a chill and an oral temperature of 104° F. On June 16 500 c.c. of blood from another B donor were given. The urine had been alkalinized prior to transfusion. Fifteen minutes later she had a chill with nausea and vomiting. The oral temperature rose to 102.4° F. The next morning she appeared deeply jaundiced. By three in the afternoon the icterus had noticeably diminished. No hemoglobin was found in the urine. Early on June 18 spontaneous labor occurred and a premature infant was delivered which soon died. The patient made an uneventful recovery. Repetition of the cross-matching showed no incompatibility.

Blood chemical studies

| Date 1936 | van den Bergh | Blood Urea Nitrogen mg % | Blood Uric Acid mg % | Blood Creatinine mg % |
|--------------|---------------|--------------------------------|-------------------------------|-----------------------------|
| June 16 | 0.3 direct | Transfusion | | |
| June 17 | 20.1 direct | | 4.2 | 1.6 |
| June 18 | 8.2 direct | | 4.8 | 1.4 |
| June 21 | 1.0 biphasic | | 3.1 | 2.0 |
| June 26 | | | 3.8 | 1.2 |

PULMONARY EDEMA FOLLOWING BLOOD TRANSFUSION

In addition to the pulmonary edema which constitutes one of the terminal features of uremia from any cause, it has been commonly recognized that overburdening of the circulation with large volumes of fluid sometimes pro-

duces the condition directly²¹ Plummer²² recently reported five deaths from pulmonary edema after blood transfusions in Charing Cross Hospital

Case 11 E S, a woman 30 years old, entered the hospital with a septicemia due to *Streptococcus hemolyticus*. She was suffering intense pain from a thrombophlebitis in a large cavernous hemangioma involving the entire right arm. The heart was normal in size and rhythm by the usual physical diagnostic criteria. There was a soft, blowing, systolic murmur at the cardiac apex. The lungs were clear. A moderate secondary anemia was present. Her blood was classified as Group A. After preliminary cross-matching on February 21, 1937, she received 500 c c of citrated blood from a Group A donor along with 200 c c of isotonic saline solution. The administration of the solutions required one hour and 10 minutes. There were no immediate symptoms but about one hour later she became extremely dyspneic and cyanotic and complained of indefinite pains in the thighs and legs. The heart appeared normal except for a rate of 130 per minute. Some coarse râles were present in the left lung. The symptoms were partially alleviated for a time by the administration of 0.5 c c epinephrine hydrochloride, 16 mg (gr $\frac{1}{4}$) morphine sulphate, and atropine sulphate 0.4 mg (gr $\frac{1}{500}$) but she died eight hours after the transfusion was begun.

The donor's and recipient's bloods were re-typed and re-cross-matched after the transfusion using the hanging-drop, Vincent open slide, and the Landsteiner centrifuge methods. No incompatibility could be demonstrated.

Autopsy The anatomic diagnoses were *Streptococcus hemolyticus* septicemia, cavernous hemangioma of right shoulder and arm, pulmonary edema and congestion. There was no cardiac dilation.

Case 12 H H, a woman, aged 43 years, had chronic glomerular nephritis with secondary anemia. Before admission she was said to have had hypertension but during her stay in the hospital the blood pressure was about 140 mm of mercury systolic and 70 mm diastolic. The heart was moderately enlarged and there was slight pitting edema of the ankles. The urine contained a moderate amount of albumin and a few leukocytes. No casts were seen. The hemoglobin measured 27 grams (Haden-Hauser), erythrocytes numbered 1,300,000 and leukocytes 21,200 per cu mm. Her blood was classified as Group A. February 22, 1937, she was given a transfusion of a mixture of 450 c c of Group A citrated blood and 150 c c of isotonic saline. When 200 c c of the mixture had been given in 45 minutes, the administration was discontinued because of severe dyspnea and cyanosis. She was given epinephrine hydrochloride and morphine sulphate hypodermically and aminophyllin (0.48 gram) intravenously. She died one-half hour after the transfusion was discontinued. Analysis of postmortem blood gave the following values: urea nitrogen 99.4 mg per cent and creatinine 11.8 mg per cent.

The recipient's and donor's bloods were re-typed and re-cross-matched after the reaction occurred but no incompatibility could be demonstrated by the hanging-drop, Vincent open-slide, or the Landsteiner centrifuge methods.

Autopsy Anatomic diagnoses—marked pulmonary congestion and edema, slight cardiac hypertrophy, chronic diffuse nephritis, anemia and hyperplasia of the bone marrow. The heart was only moderately dilated. It is very difficult to account for the production of pulmonary edema by increasing the blood volume by only 200 c c.

RETINAL HEMORRHAGE FOLLOWING TRANSFUSION

Ophthalmologists are acquainted with the fact that blood transfusions are occasionally followed by retinal hemorrhages²³. The only statistical study available is that of Messinger and Eckstein²⁴ who examined the retinæ of 60 individuals preceding and following transfusion with com-

patible blood. Ten of these patients developed retinal hemorrhages after transfusion. There was a high incidence of blood dyscrasias in the series studied, however, and the hemorrhages were most common in this group. Walker,²⁵ of the Department of Ophthalmology of this hospital, is at present engaged in a similar study of cases receiving transfusions. The incidence of blood dyscrasias in his series is very much lower and, so far, out of over 80 cases examined only one has developed retinal hemorrhages. The cases to be reported here are not included in his series.

CASE REPORTS

Case 5 This has been reported above. She developed retinal hemorrhages after transfusion and during the time that there was evidence of renal insufficiency from the chronic nephritis as well as from the superimposed transfusion oliguria.

Case 3 This man had pernicious anemia and received the incompatible blood before admission to the hospital. He had extensive retinal hemorrhages but whether they followed transfusion is not known.

Case 13 A W, a woman of 69 years, had an anemia of unknown etiology. The hemoglobin was 30 per cent (Sahli), erythrocytes numbered 1,060,000 and leukocytes 4,800 per cu mm. The leukocytes were predominately lymphocytes with an occasional myelocyte and blast cell. The blood Kahn and Wassermann tests were negative. Achlorhydria was demonstrated after histamine stimulation. The tourniquet test for petechiae, the bleeding and coagulation time, and erythrocyte fragility tests were all normal. The clot was non-retractile. The blood platelets were 0.09 per cent (Van Allen), and the hematocrit 12 per cent. Liver therapy did not stimulate reticulocytosis. There was a continuous low-grade fever. The tentative diagnosis was aleukemic leukemia, lymphatic type. Before transfusion fairly extensive hemorrhages were seen in both retinæ but the maculae were not involved. The patient's blood was classified as Group A and on November 27, 1935, she received 500 c c of citrated Group A blood in 45 minutes, after preliminary cross-matching. Thirty minutes after transfusion there was a violent chill and the rectal temperature rose to 105° F. The next morning she complained of inability to see objects at a distance of 18 inches. Ophthalmoscopic examination revealed great extension of the pre-retinal hemorrhages to include both maculae. There was no hemoglobinuria or icterus and re-cross-matching of bloods by microscopic and macroscopic methods revealed no incompatibility.

She received 500 c c of blood from another Group A donor on December 3, with no reaction. On December 10 the bleeding time had become greatly prolonged and petechiae were elicited by the tourniquet test. On December 13 a transfusion of 400 c c of blood from another Group A donor had to be discontinued because of a chill and rectal temperature of 104.5° F. She died December 16, apparently of bronchopneumonia. No autopsy could be obtained. No incompatibility of bloods could be demonstrated in the laboratory after any of the transfusions.

SUMMARY

Mortality Seven deaths directly attributable to blood transfusions occurred in a series of approximately 3,500 transfusions. Five persons died of renal insufficiency and two of pulmonary edema (Case 3 should not be included in the statistics because the transfusion was given in another hospital). The mortality for blood transfusion in this series was, therefore, 0.2 per cent. Only one individual developing renal insufficiency in

this series recovered (Case 6) and this could not clearly be attributed to any treatment received

Transfusion of Incompatible Blood Many authors¹ have emphasized the importance of using typing sera of high titer. This is further illustrated by the donor in Cases 2 and 4 who gave blood as a Group O and later, with stronger sera, was found to belong to Group A. We have had five or six individuals on the donor list who were originally thought to belong to Group O but when retyped with stronger sera were found to belong to other groups, mostly to Group A.

The necessity for the cross-matching of bloods in addition to the typing is well recognized. This is further illustrated in Cases 5 and 9 where the recipients were found to belong to atypical blood groups which were not differentiated by strong typing sera and in which errors apparently occurred in the preliminary cross-matching.

Interviews with interns graduated from various medical schools and a review of their performance in managing large numbers of transfusions lead to the following conclusion. Either the importance of the laboratory technic of determining blood incompatibility is under-emphasized in undergraduate medical education or the technic itself is too difficult to be entrusted to those with the laboratory training of the average intern. Neither of these views is implied in the discussions contained in the standard textbooks on laboratory diagnosis.

It seems necessary further to emphasize the dictum that a transfusion should be discontinued immediately upon the occurrence of any unusual symptoms. This is illustrated by Cases 2 and 5 in which symptoms were ignored or considered insignificant and in Case 8 in which the transfusion was discontinued in time to prevent serious results.

Hemolytic Transfusion Reactions We have collected considerable data regarding the van den Bergh reaction in cases of hemolysis (Cases 1, 5, 6, 8, 10). These would indicate that for the first day or so after hemolysis occurs the van den Bergh is either "direct" or "biphasic" and may attain values as high as 20.1. It promptly thereafter changes to an "indirect" reaction within the limits of normal. This conclusion coincides with the statement of Mann and Bollman.²⁶

Cases 8 and 10 and the experimental demonstration of a renal threshold for hemoglobin justify the conclusion that the most reliable diagnostic criterion of a hemolytic transfusion reaction is the occurrence of hemoglobin-tinged blood serum one or two hours after the transfusion rather than the appearance of icterus or hemoglobinuria.

Both from our experience and that of other writers, we must conclude that the present laboratory tests as routinely applied involving cross-matching by the hanging-drop, the Vincent open-slide, and the Landsteiner centrifuge methods are inadequate in certain instances to detect incompatibilities of bloods which after transfusion become manifest clinically. This is especially illustrated by Case 6.

Renal Insufficiency from Blood Transfusion The various theories to account for the mechanism of this phenomenon are discussed. If it is admitted that hemolytic reactions can occur without hemoglobinuria, the dogma that anuria occurs only after hemolysis cannot be proved or disproved by our studies or by the cases reported elsewhere in the literature. In all of our cases of renal insufficiency in which the blood serum was examined promptly, the van den Bergh reaction was compatible with the diagnosis of hemolysis.

In view of our ignorance of the mechanism of the renal damage it would seem that the only safe procedure at present is to alkalinize the urine prior to transfusion. This has been shown to prevent obstruction of the renal tubules by hemoglobin in rabbits and dogs. It must be assumed for the present that this mechanism also operates, at least occasionally, in humans.

The treatment of this type of renal insufficiency is at present unsatisfactory. Some cases recover spontaneously and others probably die regardless of any known therapeutic procedures. We have not attempted decapsulation of the kidneys but it has been reported to have failed in some cases. Apparently more efficient treatment depends on increasing our knowledge of the pathogenesis.

The Use of "Universal Donors" This procedure is fraught with danger unless the agglutinins of the donor have been previously titrated and found to be weak (Case 8).

Pulmonary Edema from Blood Transfusion This complication of blood transfusion has been neglected in the medical literature. It is not the result of the administration of incompatible blood. On theoretical grounds, it would seem to be due to overburdening of the right side of the heart although it is difficult to ascribe this explanation in Case 12 where only 200 c c of fluid apparently produced death. It is possible that an amount of pulmonary edema small enough to escape detection was previously present. At autopsy the heart in Case 12 was only moderately dilated and in Case 11 no dilation could be found. Patients with cardiac damage and those with nitrogen retention from any cause apparently tolerate transfusions poorly.

Retinal Hemorrhages after Blood Transfusion In patients having diseases which predispose to retinal hemorrhage, as in blood dyscrasias, transfusion is sometimes followed by bleeding into the macular region causing serious impairment of vision (Cases 3, 5, and 13).

Diagnosis of Transfusion Reactions by the Pathologist The importance of careful postmortem examination has been stressed. Autopsies of patients receiving transfusions are occasionally very illuminating if the pathologist is familiar with the morbid anatomy of transfusion reactions. This is especially true in cases of renal insufficiency. Cases 3 and 7 were first diagnosed by the pathologist when the condition had not been suspected clinically.

CHRONIC ATROPHIC ARTHRITIS *

By H E THOMPSON, M D , B L WYATT, M D , F A C P , and
R A HICKS, M D , *Tucson, Arizona*

THERE has been sufficient interest and study of arthritis to warrant a somewhat detailed report on chronic atrophic arthritis. This terminology is synonymous with Type I, chronic infectious, chronic proliferative, chronic rheumatoid arthritis and arthritis deformans.

This study includes an admission analysis of 343 patients and a treatment and follow-up summary of 274 patients seen at this clinic. It does not include 280 patients a recent study of whom has been reported^{1,2}

The patients in this study include only those having a definite chronic atrophic arthritis of the non-specific type. All other types were carefully excluded. The availability of data elsewhere^{3,4,5,6,7,8,9} justifies the omission in this paper of discussion of the diagnostic criteria of atrophic arthritis.

A thorough history, physical and laboratory examinations were done on these patients on admission and at monthly intervals thereafter. The laboratory data required were complete blood counts, sedimentation rates (Westergren), agglutination titers of serum (reaction with standard strains of streptococci of the hemolytic and viridans type), complete stool and urine examinations and cultures and smears from foci of infection. In addition, roentgenological examination (fluoroscopic and films), metabolism tests, and blood chemistry determinations were done when indicated.

The findings on admission are summarized in table 1. They will be discussed under their separate headings.

TABLE I
General Summary

| | Males | Females | Both sexes |
|---|-------------|--------------|--------------|
| Total patients seen | 153 (44.6%) | 190 (55.4%) | 343 |
| Total patients admitted | | | 274 (76.96%) |
| Total patients diagnosis only | | | 69 (23.04%) |
| Average age when seen | 42.7 years | 44.2 years | 43.56 years |
| Oldest patient | 89 years | 78 years | 89 years |
| Youngest patient | 18 years | 6 years | 6 years |
| Average age at onset | 36.59 years | 37.28 years | 36.93 years |
| Average duration of arthritis when seen | 6.11 years | 6.92 years | 6.51 years |
| Patients showing deformities | 91 (44.66%) | 115 (55.34%) | 206 (60.06%) |
| Patients showing no deformities | 62 (45.25%) | 75 (54.75%) | 137 (39.94%) |
| Patients having focal infection | | | 198 (57.73%) |
| Patients with no demonstrable focal infection | | | 145 (42.27%) |

* Received for publication April 26, 1937
From The Wyatt Clinic and Research Laboratories, Tucson, Arizona
Presented in part before the Chicago Orthopaedic Society, April 1937

INCIDENCE BY SEX

Out of 343 patients 44.6 per cent (153) were males and 55.4 per cent (190) were females. These percentages do not show as great a preponderance in the female as compared to the males as the figures quoted by some investigators¹⁰, however, they are closely comparable to the percentage incidence reported by Weatherby¹⁰. All agree that atrophic arthritis is higher in the female¹¹.

AGE OF PATIENTS AT THE ONSET OF ARTHRITIS AND AGE ON ADMISSION

The average age of male patients at the onset of the disease was 36.59 years, for females the average age at onset was 37.28 years, with an average age of 36.93 years for both sexes. The latter figure represents a mean between two extremes of age, namely, two years and 71 years. The highest incidence for both sexes was between the third and fourth decades of life. No important difference in sex in this regard was noted.

The average age of patients when first seen at this clinic was for males 42.7 years and for females 44.2 years with an average age of 43.56 for both sexes. The oldest patient seen was a male of 89 years, the youngest patient seen was a female aged 6 years.

The above summary indicates that although the highest incidence is between the third and fourth decades of life the disease may occur at any age and in either sex. Furthermore, no one age group is exempt.

DURATION OF ARTHRITIS PRESENCE OF DEFORMITIES

The chronicity of atrophic arthritis is quite evident when one notes the duration of the disease in this group of patients. The average durations of the arthritis when these patients were first seen were for males 6.11 years and for females 6.92 years, with an average duration of 6.51 years for both sexes.

Deformities were present in 60.06 per cent of these patients. The females exhibited a slightly higher incidence (55.34 per cent) than the males (44.66 per cent).

From this it is apparent that this disease is more or less progressive and that deformities are prone to occur. A study of the case histories of these patients indicates that the majority were "last resorters"—patients who had been under the care of competent men elsewhere—patients who had been to various spas and health centers—patients who had tried various patent medicines or other remedies obtainable—patients who came here with the final fond hope that the climate in some miraculous manner would alleviate their suffering, restore damaged joints to function or even "cure" their arthritis. It has been our unhappy experience to see patients who were sent or came here for climatic benefit during the active stage of the disease who did not think it necessary or were not advised that competent medical

supervision should be continued as long as the arthritis is active. It is amazing how fast these people without adequate treatment develop deformities. It finally becomes apparent to the patient that he is getting worse and he presents himself for medical care. How much easier it is to prevent than correct a deformity, but successful prevention is absolutely dependent upon early continuous treatment.

We must ever be on the alert—to have sufficient foresight to know that without adequate management flexion contractures, ankylosis and deformities will probably occur. In addition, it is highly important that these patients remain a sufficient time at one place, otherwise they will develop their deformities during their pilgrimage from doctor to doctor.

FOCAL INFECTION

An extensive and thorough search for foci of infection was made in this study. Out of this group 57.73 per cent (198 patients) were found to have definite demonstrable focal infection. This is a surprisingly high incidence in view of the chronicity of these cases and the low incidence reported by other workers.¹²

In table 2 are indicated the sites of the focal infections.

TABLE II
Location of Foci of Infection

| Total cases 343 | Cases with foci 198 | | 57.73 per cent | |
|---------------------------|---------------------|-------|-----------------|-------|
| Throat or pharynx | alone | 19.0% | with other foci | 23.0% |
| Sinuses | alone | 9.0% | with other foci | 19.0% |
| Gingival tissue | alone | 5.5% | with other foci | 13.0% |
| Tonsils or remnants | alone | 8.0% | with other foci | 10.0% |
| Teeth | alone | 6.5% | with other foci | 10.0% |
| Urinary tract | alone | 8.0% | with other foci | 10.0% |
| (Lower) Respiratory tract | alone | 5.5% | with other foci | 5.7% |
| Female pelvis | alone | 4.0% | with other foci | 4.5% |
| Prostate | alone | 4.0% | with other foci | 4.0% |
| Gall-bladder | alone | 1.5% | with other foci | 1.5% |
| Colon | alone | 0.0% | with other foci | 1.0% |
| Miscellaneous | alone | 0.0% | with other foci | 0.0% |

In 80 per cent of the cases the foci were found alone or in combination from the respiratory tract up. Of this 80 per cent localizations in the throat or pharynx were most commonly observed. Sinuses, gingival tissue, teeth and respiratory tract followed in the order of their respective incidence. In the remaining 20 per cent the urinary tract was involved in one half of the cases, followed by female pelvis, prostate, gall-bladder and colon in the order presented.

The highest incidence in this series is that of the throat and pharynx. The relatively low incidence of infection in tonsils as compared to that found

by other workers⁹ is due to the fact that most of these patients had had their tonsils removed

Inflammation of the throat is often so slight as to escape the notice of the physician and patient. Rarely does the patient complain of a sore throat. We have cultured all these throats. In a large number of instances the flora have contained a predominating or even pure culture of hemolytic streptococci. In search for other foci one must look to tonsils or tonsillar remnants, the sinuses, the gingival tissue and teeth. The examination of the teeth and gingival tissue should include not only roentgenological study but also careful direct examination and transillumination. The gingival tissue should be massaged and carefully inspected for pus pockets and faulty dental repair. Cultures should be done on all suspicious areas. Once a focus of infection has been found it is always necessary to determine by further search if it is primary or secondary.

It has been repeatedly brought to our attention in this study that (1) periodontoclasia may be the only focus present, that (2) the incidence of gingival infection is higher than that of dental abscess, and that (3) roentgenological examination of the teeth will but in a few cases definitely demonstrate periodontal infection.

Although sinusitis has been looked upon as a fairly benign factor in atrophic arthritis, the high incidence reported here may indicate otherwise. Its importance has been indicated by the studies of others^{13, 14}.

In most of these foci we were able to demonstrate streptococci, usually of the hemolytic type, except in the infections of the urinary tract. Cholecystographic and non-surgical gall-bladder drainage evidence of gall-bladder infection was confirmed by direct examination and culture of tissue removed at operation.

The actual significance of these findings is not clear—there has been no direct evidence of their relationship to atrophic arthritis, particularly in long existing cases, yet we are firmly convinced that focal infection is important even in chronic cases. If one considers atrophic arthritis as due to three general factors, namely, infectious, external and constitutional, he may hope to remove the first and indirectly benefit the third. We have in several instances removed foci of infection in long standing cases with remarkable results. It has happened too frequently to be coincidental, however, we are at a loss to know whether the effect was due to removal of the infectious factor or to the constitutional improvement. Until we have direct evidence of the relationship of bacteria to this disease little can be stated with assurance, although it may be discussed at length.

TREATMENT

This group of patients has received a composite treatment as indicated in table 3. We wish to emphasize that no single treatment is specific in this group.

TABLE III
Treatment Summary

| | | |
|------------------|--------------------------|-----|
| Patients treated | | 274 |
| Receiving | Physiotherapy } | |
| Receiving | Dietotherapy } | 201 |
| Receiving | Heliotherapy } | |
| | or | |
| Receiving | Combination of above | 69 |
| | or | |
| Receiving | None of above | 4 |
| Receiving | Antigen, intravenously | 122 |
| Receiving | Vaccine | 40 |

| Receiving | Both | 15 |
| | Removal or treatment | |
| Receiving | Focal infection | 198 |
| | Non-operative orthopedic | |
| Receiving | Treatment | 118 |
| | Operative orthopedic | |
| Receiving | Treatment | 11 |
| Receiving | Blood transfusions | 48 |

An ideal treatment plan embraces a composite program directed to the relief of pain, the amelioration of clinical manifestations, the arrest, the prevention and the correction of deformities. In table 4 an outline of treatment is given. Over a period of several years in which such a procedure has been followed we have found it most valuable.

The treatment of atrophic arthritis involves not only the active treatment but also the prophylactic treatment. We have little information in regard to the prevention of this disease, but we are convinced that the incidence of chronic cases is much too high. Unfortunately we have no means at our disposal to say which patient under certain circumstances will develop arthritis and which one will not.

Constitutional treatment is an important phase of active therapy. It involves treatment or removal of focal infections, rest, physical therapy, dietotherapy, blood transfusions, heliotherapy and climatotherapy.

Of great interest is the fact that an intercurrent jaundice may produce a remission in arthritis. For the past year and a half we have been working on the problem of "therapeutic jaundice." Recently we have evolved a technic whereby a "therapeutic jaundice" may be induced safely and with very slight reaction, either local or general. The importance of jaundice in arthritis has already been discussed by various authors in the literature. We will shortly present a paper on this subject.

REMOVAL OR TREATMENT OF FOCAL INFECTIONS

In all patients in this group in whom a definite focal infection was demonstrated this focus was treated or, when feasible, removed. Out of this group 82 per cent exhibited moderate to marked improvement on discharge, while 18 per cent of this group exhibited slight to no improvement.

TABLE IV
Treatment of Atrophic Arthritis

An ideal treatment plan embraces a composite program directed to the amelioration of the manifestations of a symptomatic and constitutional disease

I Prophylactic

A Removal or correction of

- 1 Infectious factors—early treatment or removal of focal infections before symptoms appear
- 2 External factors—avoidance of chilling, damp climates, trauma etc
- 3 Constitutional factors—proper attention to constitutional inadequacy—conversion of the “arthritic soil” into a “non-arthritis soil” by detailed attention and treatment

II Active

A Constitutional

- 1 Treatment or removal of focal infections
- 2 Rest
- 3 Physical therapy
- 4 Diet
- 5 Transfusions
- 6 Heliotherapy
- 7 Climatotherapy

B Local—Prevention of Deformities

- 1 Rest to inflamed joints, either bed rest or by proper orthopedic appliances or both
- 2 Motion—early through painless range to prevent ankylosis, later active exercise to restore muscle tone

C Correction of Existing Deformities

1 Non-operative

- a Traction
- b Cast wedging
- c Turnbuckle and other adjustable splints
- d Manipulation
 - 1 With anesthesia
 - 2 Without anesthesia

2 Operative

- a Arthroplasty
- b Capsuloplasty
- c Tendon lengthening or shortening
- d Osteotomy
- e Synovectomy
- f Arthrodesis, etc

D Antigens and Vaccines

E Drugs

1 Non-toxic

- a Salicylates
- b Iron
- c Rarely opiates (caution)

2 Toxic or of doubtful value

- a Gold salts
- b Sulphur
- c Chaulmoogra oil
- d Arsenicals
- e Cinchophen and derivatives
- f Massive dose of vitamin products
- g Colchicine
- h Snake venom
- i Bee sting extracts, etc

on discharge Improvement was noted in a relatively larger percentage of patients treated for their focal infection than of the patients who had no focal infection

As we have stated previously we feel that treatment or removal of focal infection is important despite some opinions to the contrary We feel, in

addition, that in these chronic cases the time of focal removal and the method used are extremely important. In certain individuals one must proceed with the greatest caution lest he do more harm than good. We have been fortunate in this regard to have experienced no severe reactions. Finally, it is very important that one discriminates between infected and non-infected tissue before removal is attempted.

REST

Rest, both local and general, is necessary in the treatment of this disease. Nearly all these patients complain of early fatigue. The patients were instructed as to the proper amount of rest during each 24 hours. Activity must be kept within the limits of fatigue. The amount of bed rest is variable. In cases with hot swollen weight-bearing joints the bed rest should be absolute until the inflammation has subsided. This may be a period of weeks or months. The joints are carried through a painless range of motion several times daily. These rest periods are always carried out with the joints in the position of extension and function and maintained in that position by the necessary appliances. Later, graduated activity and exercise may be permitted. There is no one treatment directed to the joints as valuable as rest. With it the inflamed joints are kept motionless and the weight bearing and movement trauma entirely eliminated. It is often surprising how well these mentally and physically fatigued patients respond to bed rest. Naturally in some cases only minimal rest is desirable.

PHYSICAL THERAPY

Nearly all these patients received physical therapy. This includes heat of all types, light, massage, water, mechanical and electrical modalities and other physical agents. These valuable adjuncts to the treatment of atrophic arthritis will not be discussed as there is a wealth of available publications on this subject^{3, 15, 16, 17, 18, 19, 20, 21}. Our staff includes two competent physiotherapists who work under direct medical supervision. With portable equipment it is possible to treat patients at home as well as at the Clinic.

We have noted in this group little benefit derived from hyperpyrexia (induced by any means). We reserve its use to gonorrheal arthritis where it is extremely valuable^{22, 23}.

The judicious use of physical therapy is important. It requires judgment and direction of administration. When so used there appears to be no doubt as to its therapeutic effectiveness.

DIETOTHERAPY

Much has been written concerning the value of diet in arthritis. Most of the patients in this study were underweight, hence they were placed upon a high vitamin, high calorie, low starch diet, supplemented when necessary (for weight gain) by milk and cream. Vitamin B was administered

routinely as wheat germ. This diet was varied occasionally to suit the needs of the individual patient. Obese patients were given the diet suggested by Pemberton⁸. It is remarkable how the doughy swelling responds to this latter diet. We have observed this same phenomenon to occur after starvation, nausea and vomiting, diarrhea and ether anesthesia. The significance of these observations has not been fully explained.

It is quite obvious that to secure constitutional improvement the underweight arthritic should gain weight, the obese arthritic should reduce. Although there are other factors concerned, dietary considerations are exceedingly important.

BLOOD TRANSFUSIONS

Blood transfusions have been extremely useful in the treatment of certain patients of this group. A total of 198 transfusions was given to 48

GRAPH 1 Showing the effect of blood transfusions upon the sedimentation rate
Sedimentation rate mm per hour (Westergren)

patients with an average of four transfusions per patient. The amount of blood given each time was from 300 to 600 c.c. or about 10 c.c. per kilo of body weight at two to six week intervals.

The effect of blood transfusions on the sedimentation rate is of interest (graph 1). It has been noted in the majority of the cases following a trans-

fusion that the sedimentation may drop to one half of its original rate. In this group this can not be accounted for solely by the improvement in the blood count. In addition, we have noted that in patients who improve the sedimentation rate following transfusions may fluctuate but the general progress is toward normal values, while in those who do not improve the sedimentation rate tends to rise toward its former level or even higher. In occasional cases the sedimentation rate may remain high even though the patient is clinically improved.

In this group receiving transfusions 66 per cent showed improvement on discharge. We do not favor blood transfusions in all cases but in certain individuals whose arthritis is particularly resistant to treatment and progressive, or who are markedly debilitated or have a persistent severe secondary anemia, transfusions are extremely valuable and should be utilized.

HELIOOTHERAPY AND CLIMATOTHERAPY

Nearly all arthritics of this type are benefited by a warm dry climate such as we have here in the southwest. It constitutes a valuable aid in the treatment of these patients who can spend a sufficient time in such a climate. It is equally true that a few are not benefited.

Heliotherapy was used in the treatment of the majority of these patients. Sun bathing was prescribed at a regular time, with duration and amount of exposure definitely indicated. There are a few contraindications to direct heliotherapy, namely, (1) the presence of fever, (2) the appearance of a general or local reaction and (3) complicating or debilitating conditions such as active tuberculosis, chronic myocardial disease, general debilitation and old age, etc. In febrile patients it is wise to give no direct heliotherapy but to utilize the indirect type. In case of a general or local reaction it is well to minimize the time of exposure, eliminate it entirely or to prescribe only indirect heliotherapy. We believe that both climate and sun are valuable agents in treatment.

LOCAL TREATMENT AND PREVENTION OF DEFORMITIES

Rest as noted above constituted an important phase of the treatment. Graduated bed rest, splinting and rest casts should be used not only at the onset but throughout the course of the disease. An arthritic joint is always a potential deformity and should be treated as such. Properly directed physical therapy is highly beneficial. Painful joints with limitation of motion and soft tissue swelling should be moved through the painless range of motion several times daily. Exercise and activity must be within limits of pain or fatigue. It is highly pleasing to note that patients can be treated throughout the course of their disease so that when activity has subsided these joints are functionally adequate—more pleasing perhaps when one realizes that, without adequate treatment over such a period, these same patients might become permanently disabled.

CORRECTION OF DEFORMITY

Because of the high incidence of deformities in these chronic cases their correction constitutes an important part of treatment. There are several non-operative methods available, namely, traction, cast wedging, turnbuckle and other adjustable splints and finally, manipulations with or without anesthesia. It seems very important that one proceed with utmost caution and with the dictum "do not harm." In addition, one must visualize as accurately as possible what the conditions will be a year or two years from the time of correction. It seems hardly necessary to mention that each joint should be studied extensively and other factors taken into consideration before correction is attempted. In our hands gentle, well-directed traction has been the method of choice. Occasionally we have found it necessary to resort to the other methods or even in some cases to discontinue correction because of a generalized or local reaction. Finally, it may be said that many deformities can not be completely corrected by non-operative methods and the procedure of choice should then be operative.

The operative treatment of deformity consists of synovectomy, arthroplasty, capsuloplasty, arthrotomy, osteotomy, arthrodesis, etc. It is well agreed that better results occur when the disease is quiescent. There are some indications, however, that these deformities may be corrected earlier, even during activity—in certain instances. Sufficient time has not elapsed to draw conclusion from our recent cases. It is worth emphasis that any corrective procedure should be preceded by an adequate period of preparation involving exercises, constitutional care and transfusions when indicated and followed by an equally persistent post-operative period of rehabilitation. If the disease is still active great care must be exercised to prevent recurrence of the deformity.

ANTIGENS AND VACCINES

As we have previously discussed vaccine and antigen therapy we will only mention again that we consider a patient suitable for vaccine or antigen when the sedimentation rate is high and the agglutination titers are low. Unfortunately there has been no diagnostic test of a reliable nature for determination of a patient's sensitivity to bacteria or bacterial products.

DRUGS

There has been a constant parade of drugs used in the treatment of arthritis. Among them may be mentioned cinchophen and derivatives, arsenicals, gold, sulphur, chaulmoogra oil, vitamin products, snake venom, colchicine and many others. There is no proof of their specific nature and there is evidence that severe toxic reactions may result from certain drugs—notably gold and cinchophen. At this Clinic we have found acetylsalicylic acid with or without some form of calcium or sodium bicarbonate

to be valuable. There are other non-toxic analgesics of acceptable value. Opiates are to be used with extreme caution and we have rarely resorted to them. Iron is of value in the accompanying anemia. It may be best given by the oral route in fairly large doses. Subcutaneous or intravenous administration of iron appears to have no advantages over the oral route and in some cases may be dangerous. There appears to be no advantage in giving salicylates intravenously as there is sufficient evidence to indicate that their irritative properties are central rather than local.

Sulphur and gold have been disappointing in our experience but we have noted some beneficial effect with massive doses of vitamin D².

RESULTS OF TREATMENT

It appeared worth while to correlate the time of treatment with the results. In addition, follow-up inquiries were sent to all of these patients to determine their progress since discharge. These follow-up reports came

TABLE V
Results and Duration of Treatment

| Progress | Number of Patients | Per cent | Duration of Treatment |
|----------------------|--------------------|----------|-----------------------|
| No improvement | 35 | 12.82% | 4.88 months |
| Slight improvement | 28 | 10.68% | 4.53 months |
| Moderate improvement | 94 | 34.18% | 7.95 months |
| Marked improvement | 116 | 42.30% | 8.20 months |

TABLE VI
Results of Follow-Up Reports

| | Number Reporting | Reported Condition 1-6 Years Later | | | | |
|--|------------------|------------------------------------|------|----------|------|------|
| | | Worse | Same | Improved | Well | Died |
| Patients showing slight or no improvement on discharge | 21 | 9 | 8 | 3 | 1 | |
| Patients showing moderate to marked improvement on discharge | 87 | 9 | 18 | 30 | 28 | 2 |
| Total | 103 | 18 | 26 | 33 | 29 | 2 |

in after an elapsed interval of from one to six years and in most of the cases the elapsed time was longer than two years.

Out of this group of 273 patients 23.5 per cent or 63 patients exhibited little or no improvement during an average treatment period of 4.6 months. One to six years later follow-up reports on 21 patients of this group were as follows: nine were worse, eight remained the same, three were better

and one was well. The remaining 76.5 per cent or 210 patients exhibited moderate to marked improvement on discharge. Six per cent or 12 patients of this group were well when dismissed. The average duration of treatment was 8.1 months. Follow-up reports one to six years after discharge on 87 of these patients were as follows: 9 were worse, 18 were the same, 30 were improved, 28 well and 2 were dead.

These results indicate that of the 76 per cent of the patients treated who exhibited moderate to marked improvement on discharge, nearly all continued to improve in the years following. Some were entirely free from their arthritis and a few were worse. Out of the group (23 per cent) who showed no improvement nearly all were worse or the same, a few were better and only one was well. It is interesting to note that the average treatment time of those who exhibited moderate to marked improvement was eight months as compared to four months for those who showed little or no improvement. We feel that the length of treatment is an important factor. Patients should understand at the beginning of treatment that the course is long and will require not a few but many months of painstaking treatment. It is hoped that the time will come when we can treat this terrible disease throughout its entire course.

SUMMARY

Admission data on 343 cases of chronic atrophic arthritis may be briefly summarized as follows: (1) Chronic atrophic arthritis runs a more or less progressive course unless treated. (2) The percentage of these patients (60.06 per cent) who showed deformities is greater than that of patients who did not. (3) All ages and both sexes were affected, the females more frequently than the males and the highest incidence was in the third and fourth decades. (4) Focal infections were found in 57.73 per cent of these patients. In 80 per cent of these cases the foci were found alone or in combination from the respiratory tract up. Foci in the throat or pharynx were those most commonly observed, followed by foci in sinuses, gingival tissue, teeth and respiratory tract in their respective order. In the remaining 20 per cent of the cases there were infections of the urinary tract in one-half, and in the remaining cases, infections of the female pelvis, prostate, gall-bladder and colon, occurring in the order of frequency given. The organism most frequently found was a streptococcus of the hemolytic type.

The treatment of this disease involves a detailed plan embracing physical therapy, heliotherapy, dietotherapy, climatotherapy, treatment or removal of focal infections, rest both local and general, the prevention and correction of deformities, bacterial antigens and vaccines, mild analgesic and anti-anemic drugs and blood transfusions.

With such a plan 76.48 per cent of the patients treated were discharged moderately to markedly improved after an average treatment period of eight months. Of this group 6 per cent were entirely well. One to six years

later nearly all this group had maintained their improvement, or were well (33 per cent), and a few were worse. In the remaining 23.52 per cent of patients little or no improvement was noted on discharge after a treatment period of four months. Follow-up on these cases indicated that most of them were the same or worse while a few had improved. This indicates that treatment of arthritis involves many therapeutic factors which must be carried over a sufficient length of time before the maximum benefit can be derived. And, finally, that there is a certain percentage of patients who become worse or who are not benefited by treatment. It is the problems of this group particularly that should be the object of further research. Perhaps it is in this group that detailed study of the "soil" will give more information than the study of the "seed."

TUMORS OF THE PULMONARY APICES AND ADJACENT REGIONS INVOLVING THE BRACHIAL PLEXUS *

By HAROLD C. HABEIN, M.D., F.A.C.P., JOSEPH M. MILLER, M.D., and JOHN C. HENTHORNE, M.D., *Rochester, Minnesota*

TUMORS which have their origin at the apices of the lung, or in the lower portion of the neck just above the clavicle, have aroused considerable interest in the past 13 years. A number of papers recently have appeared, including reports of cases that have been similar to those in the original group reported by Pancoast in 1924.

The tumors, Pancoast reported, occurred at the apices of the lungs and produced a characteristic group of clinical symptoms. Pancoast considered this type of tumor to be a distinct clinical entity and gave it the name, "superior sulcus tumor." In 1932 he reported four more cases. His criteria for diagnosis were (1) roentgenologic evidence of a new growth at the apex of the lung, (2) homolateral pain referred along the distribution of the involved nerves of the brachial plexus, (3) atrophy of the small muscles of the hand of the side affected, (4) early development of a homolateral Horner's syndrome, (5) roentgenologic evidence of destruction of adjacent ribs and vertebrae.

Pancoast first thought these tumors to be of pleural origin but later he considered that they might be branchiogenic, arising from the fifth branchial pouch. It may be noted, at this point, that several conditions may produce the symptom-complex of pain of the homolateral shoulder and arm and cervical sympathetic paralysis, such conditions are neoplasm of the spinal cord, meninges, or cervical vertebrae, or cervical ribs or trauma. Cervical sympathetic paralysis alone may be caused by tumors of the neck, aneurysm, enlarged lymph nodes, mediastinal neoplasm, tuberculosis, and trauma.

To date, 34 cases of this unusual syndrome have been reported, 26 more or less completely. It is interesting, however, that Hare, in 1838, in addition to describing a peculiar condition of the eye, which Horner later elaborated, also gave particulars of a "glandular scirrhus in a male", the picture closely paralleled that discussed here.

Excerpts from Hare's paper follow: "He had been attacked a month before with pain, tingling, and numbness along the course of the ulnar nerve of the left arm, which was most severe at the elbow, where there had also been some swelling and redness. There was, besides, pain through the left shoulder, extending across the chest to the opposite side, and upwards to the left eye and teeth of that side. The tongue was clean, appetite good, no cough or physical sign of pulmonary disease. After a

* Submitted for publication August 19, 1937

careful examination, the only cause that could be discovered to account for his symptoms was a small tumor, situated in the 'inferior triangular space' on the left side of the neck, which it was possible might be producing some pressure on the origins of the nerves going to form the brachial plexus

In addition to the foregoing symptoms the pupil of the left eye became contracted and the levator palpebrae ceased to perform its office "

Postmortem inspection revealed "a glandular scirrhus" at the base of the neck, which involved the major structures of that region, and extended downward into the superior mediastinum The pathology and the origin of the "scirrhus" were not recorded

This century-old report justifies the conclusion that tumors, whether primary in the cervical region, such as those arising from the fifth branchial pouch, or from the pulmonary apex, or metastatic cervical tumors, or neoplasms that infiltrate the cervical region from nearby structures will produce the characteristic group of symptoms and signs to which Pancoast called attention A brief review of the literature shows that in Pancoast's cases 6 and 7 the symptoms may have been caused by metastasis from a carcinoma of the uterine cervix The question of metastatic tumor may again be raised concerning the first case reported by Browder and DeVeer, while their fifth case was one of thymic carcinoma Frost and Wolpaw reported an instance in which a sympathoblastoma arising from the inferior cervical ganglion was the etiologic agent A squamous cell carcinoma of unknown origin was the cause of the "Pancoast syndrome," as reported by Graef and Steinberg

General agreement now exists that the symptoms presented by a primary apical tumor are far different from those expected from a neoplasm situated at the tracheal bifurcation Usually the symptoms of hilar tumor are cough, hemoptysis, recurrent attacks of fever and loss of weight If there is a history of unexplained pain in the thorax or shoulder, the lungs and cervical region should be carefully examined for tumor

To produce the Pancoast syndrome, the neoplasm must involve the brachial plexus, which has its origin in the fifth, sixth, seventh, and eighth cervical, and first thoracic segments of the spinal cord Lesions which affect the ulnar nerve, which arises from the eighth cervical and first thoracic segments and traverses the medial cord of the brachial plexus, will implicate the small muscles of the hand The sympathetic supply to the face and eye arises from the upper thoracic segments Horner's syndrome, in which there is paralysis of the dilator fibers to the iris and of the superior tarsal muscle, thus causing ptosis of the eyelid, and paralysis of Mueller's retro-orbital muscle, thus causing enophthalmos, is produced in the cases under discussion by neoplastic involvement of, or pressure on, the cervical sympathetic chain, which lies anterior to the cervical vertebrae Sweating is absent over the region of distribution of the affected nerves and a high cutaneous temperature and hyperemia are found in the same region

CASE REPORTS

Case 1 A white woman who presented many of the typical features of this syndrome, recently was observed at The Mayo Clinic. The patient was 64 years of age and was admitted with a history of dull, aching pain of six months' duration, the pain was in the left side of the thorax and extended to the left shoulder and arm. One year before her admission she had noted that her left eye was somewhat smaller than her right eye (figure 1). Diplopia had been present at intervals during this period. For six months she had noticed weakness, tingling and numbness of the left hand. She had lost 50 pounds (23 kg). Cough, bloody expectoration and fever were absent.

FIG 1 Horner's syndrome

Physical examination revealed left enophthalmos, narrowing of the palpebral fissure and unequal pupils, the right pupil was larger than the left. The ocular fundi were normal. The head was inclined to the right and the left supraclavicular fossa was fuller than the right. Left cervical and axillary lymph nodes were enlarged and firm. The thyroid gland was normal in size but the trachea was to the right of the midline. Laryngoscopy revealed normal vocal cords. Slight pulsation was present under the left clavicle.

Pulmonary percussion revealed left apical dullness. On auscultation, bronchial breathing, but no râles, were heard in the same region. The remainder of the pulmonary fields was clear and evidence of pleural fluid was absent.

Definite enlargement of the areas of dullness over the heart and great vessel dullness also were present. A loud, systolic murmur was audible at both the apical and aortic areas, this was accompanied by a thrill over the great vessels. Blood pressure, read on the right arm, was 110 mm of mercury systolic and 70 diastolic,

FIG 2 Shadow in left apical region

a reading could not be made on the left arm because of extreme hyperesthesia. The radial pulse was definitely stronger on the right.

Pelvic examination revealed a cystic mass on the right, about 8 cm in diameter, and this was considered benign.

The left interosseous muscles, the extensor muscles of the wrist and the biceps brachii were definitely weak. Examination of the blood disclosed moderate anemia and negative Kline, Kahn, Hinton, and Wassermann tests.

There was a large, radiopaque area in the left apical region, continuous with

the shadow of the great vessels (figure 2). Apparently the ribs or vertebrae were not involved by a neoplastic process. Definite thickening of the apical portion of the parietal pleura, extending to the fourth rib posteriorly, was seen under the roentgenoscope.

Necropsy was performed one day after the death of the patient and about 10 weeks after her dismissal from the clinic. The most striking pathologic change

FIG 3 Carcinoma of upper lobe of left lung and pleural implants

was that the upper lobe of the left lung was entirely replaced by a firm, white tumor which extended anteriorly over the pericardium and about 2 cm to the right of the median line (figure 3). The tumor also extended into the neck, lateral to the left lobe of the thyroid gland, where it invaded the left subclavian vein and brachial plexus. The bodies of the seventh cervical and first thoracic vertebrae were involved in the neoplastic process. The main tumor measured 17 by 17 by 15 cm. The cut surface was pinkish white, mottled with scattered yellowish areas of necrosis.

There was extensive metastasis to the pleurae of both lungs and to the hilar nodes. The liver also was the site of metastasis. Of further interest were calcareous changes in the aortic valve ring and a right parovarian cyst which had given rise to clinical physical signs. Terminal phenomena had consisted of severe cystitis, bronchopneumonia and left empyema. There was rather extensive chronic tuberculosis of nodes at the hilus of the lungs and there were tuberculous masses, apparently

FIG 4 Nerve of brachial plexus invaded by carcinoma

quiescent, of the liver and spleen. Microscopically, the tumor was a squamous cell carcinoma. Figure 4 represents a section of the tumor as it involved the nerve bundles of the brachial plexus. Sympathetic nerve fibers also were involved.

Case 2 A second case which illustrates the point that any neoplastic involvement of the brachial plexus will produce the characteristic symptoms is that of a white man (figure 5), 61 years of age, who gave the following history. He had lost 60 pounds (27 kg) and considerable strength in about 10 months preceding his admission at the clinic. He had had moderate pain in the left lower part of the thorax, but cough or hemoptysis never had been present. The left pleural cavity has been aspirated 10 times in two months, the greatest amount of fluid obtained at any one time had been 84 ounces (2520 cc). The fluid was the color of honey and did not contain blood that could be detected macroscopically. Guinea-pigs had been inoculated to determine if the fluid contained acid-fast microorganisms, results had been negative. Four months prior to the time of admission the man had noted a somewhat tender, firm mass in the left side of the thorax. Pain in the

left elbow had been present at irregular intervals for three months and the left arm had become weak. There had been no numbness or tingling of the left upper extremity.

The patient was somewhat emaciated. The left pupil was slightly smaller than the right and enophthalmos, grade 1, was present. A large, solid mass extended from the left axilla to the crest of the left ilium. Resonance over the left lung was diminished, tactile fremitus was absent, and breath sounds were distant. The right pulmonary field was normal. Heart sounds were of fair quality and murmurs were

FIG 5 Appearance of patient and extent of lesion

not heard. The liver was enlarged so that it extended as far as the width of three fingers below the costal margin but the spleen was not palpable. The left axillary and the inguinal lymph nodes on both sides were enlarged and firm. On rectal examination, the nodes at the bifurcation of the aorta also were found to be enlarged. Moderate atrophy of the left interosseous muscles was present.

Stereoscopic roentgenograms of the thorax gave evidence of density throughout the lower two-thirds of the left lung, apparently without displacement of the heart or mediastinum. Very slight anemia was present but the sedimentation rate was

elevated to 60 mm per hour Examination of a stained blood smear did not disclose myeloid immaturity

Microscopic examination of a lymph node removed from the left axilla revealed the process to be an adenocarcinoma, grade 3 (figure 6)

In table 1, the majority of the completely reported cases are summarized Among other cases about which incomplete details are given are the fol-

* Patient presented clinical and roentgenologic findings in every way typical of those described by Pancoast

present over this area and a Horner's syndrome was found. Pulmonary signs were not present. Necropsy confirmed the clinical findings.

SUMMARY AND CONCLUSIONS

1 Two cases of Pancoast's "clinical syndrome" are presented and available published reports of cases are summarized.

2 Certain definite characteristics of these cases, owing to involvement of the brachial plexus are (a) pain in the thorax or the arm, or both, (b) cervical sympathetic paralysis, (c) weakness or atrophy of the muscles of the extremity affected.

3 Absence of a history of cough, hemoptysis, and recurrent chills and fever does not militate against a diagnosis of primary pulmonary neoplasm. This point is well illustrated by the first case cited.

4 In all cases in which there is obscure pain in the shoulder and in which other parts are negative to examination, roentgenologic examination of the thorax should be made, especially if evidence of cervical sympathetic paralysis is present. Pulmonary neoplasm is not to be immediately excluded because of lack of the usual symptoms.

5 Metastasis from tumors at any point in the body, if they involve the brachial plexus, will produce the characteristic chain of symptoms noted.

6 The available reported cases of this syndrome are briefly summarized.

CIRCULATION TIME AS A DIAGNOSTIC AID IN HYPERTHYROIDISM *

By SAMUEL J. GOLDBERG, M D , F A C P , *Philadelphia, Pennsylvania*

THE satisfactory results of present day treatment of hyperthyroidism make it essential that an accurate diagnosis be made before the late effects of the disease damage the heart and other viscera. The widespread use of basal metabolism equipment indicates the acceptance of this principle by the medical profession.

It is well known, however, that increased basal metabolism is not always synonymous with hyperthyroidism. There are a number of conditions which may at one time or another in their course exhibit such elevations in metabolism. This may be noted in heart failure, in some cases of hypertension, during the course of fevers, leukemia, polycythemia, and in certain emotional states with or without evidence of disturbance of the vegetative nervous system.

The converse, hyperthyroidism with normal basal metabolism, is more rarely met with. Nevertheless, genuine instances have been reported in which the basal metabolic rate has been normal throughout the entire course of the disease.¹ Likewise, the diagnosis in an otherwise typical case may be temporarily obscured by the effects of previous iodine therapy. These considerations indicate the need for other methods of approach, in evaluating the state of thyroid function, than a study of the metabolism alone.

The work of Hurxthal² and others has established the fact that the cholesterol content of the blood plasma bears a somewhat approximate inverse relationship to the degree of thyroid function. While this is not altogether reliable in the individual case, it is generally agreed that in myxedema the blood cholesterol is usually elevated, while in cases of severe hyperthyroidism, it is likely to be low. The wide range of normal values for blood cholesterol renders this method less useful in the border-line case.

About 10 years ago, Blumgart began his studies on the velocity of the blood flow. After developing suitable clinical methods for determining the speed of the circulating blood, he was able to demonstrate that there is a slowing of the pulmonary blood flow in myxedema and an increased rapidity of flow in thyrotoxicosis.³ The latter is reflected clinically in the increased pulse rate, pulse pressure, and stroke volume of the heart in hyperthyroidism. A partial explanation of the need for this increased blood flow is in the increased oxygen demands of the tissues in this disease. The red blood cells must be transported to and from the pulmonary capillaries with greater velocity in order to carry to the tissues the greater quantities of oxygen required. However, there appears to be an additional circulatory stimulant

* Received for publication August 24, 1937
From Medical Service No. 2 The Mount Sinai Hospital

in hyperthyroidism which is not present in other states of increased metabolism not of thyroid origin. The latter conditions show no change in circulation time.⁴

The lack of convenient and practical methods for determining the blood velocity delayed the general adoption of this procedure into clinical medicine. However, there have appeared a number of papers dealing with the circula-

FIG 1

tion time in normal subjects, in patients with heart failure, and in instances of pulmonary disorders which might be confused with heart failure.⁵ Blumgart,³ Gargill,⁶ and Tarr, Oppenheimer and Sager⁶ have studied small groups of cases of thyroid disease from the point of view of the circulation time, and have been able to show that the circulating blood flow is more rapid in hyperthyroidism. When heart failure develops in such cases, the blood flow slows up, at first manifesting what appears to be normal velocity, and when the heart failure becomes progressively more severe, the readings approach those observed in heart failure from other causes. It is probable that slowing of the blood velocity is the earliest reliable sign of heart failure and often precedes the development of symptoms.

In a previous report, I described a simple clinical method for determining circulation time, employing calcium gluconate.⁷ The patient reclines, with the arm at the level of the right auricle, 2.5 c.c. of 20 per cent calcium

gluconate solution,* or 5 c c of 10 per cent solution, are injected into a vein at the elbow as rapidly as possible through an 18 gauge needle. The end point is that moment at which the patient first experiences an intense sensation of heat in the mouth and tongue. The term circulation time indicates the time required from the arm to the tongue (the moment of injection to

the moment of perception). This corresponds to the path traversed by the material through the peripheral venous circuit, through the lungs, to the left heart and finally to the first peripheral arterial capillary bed off the arch of the aorta, where it is perceived as a sensation of heat in the mouth. It

* Neocalglucon 20 per cent solution, supplied through the courtesy of the Sandoz Chemical Works, Inc.

should be measured accurately with a stop watch. The sensation descends rapidly downward, following the path of the arterial circulation. In more than 500 patients observed during the past two years, we have found this method accurate, practical and safe. There have been no accidents, no important subjective discomfort, no venous thrombosis, and no sloughs.

Average Circulation Time of 72 cases 8.8 ± 0.9 seconds

In our previous report, we established the normal arm to tongue circulation time in 60 patients to range from 10 to 16 seconds, with an average normal of 12.5 ± 1.0 seconds. These tests were not performed under basal conditions, but a short period of rest in the reclining posture was required. It was found that the pulse rate did not influence the circulation time, as cases of paroxysmal tachycardia showed normal blood velocity, but that, in common with metabolism tests, it was occasionally affected by emotional states, particularly apprehension. Under these circumstances, the reading may be verified on the following day. Normal circulation speed was found

in hypertension, bronchial asthma, nephritis with edema, and in well compensated valvular heart lesions. The circulation time was shorter in hyperthyroidism, fever and anemia and was prolonged in heart failure and in myxedema.

Including the 17 cases previously reported, we now present circulation time studies in 72 cases of hyperthyroidism. Most of these patients were being prepared for operation and the diagnosis was later proved histologically. Some were observed in the office at the time metabolism tests were being made. All patients were carefully studied clinically and by repeated metabolism tests. In many instances, cholesterol estimations were made. The average circulation time for the 72 cases was found to be 88 ± 0.9 seconds, the variation being from 6.3 to 12.0 seconds. The latter reading was encountered in a patient with severe muscular weakness, and an enlargement of the liver that could not be definitely attributed to heart failure. It should be remembered, however, that a relative slowing of the circulation in a patient with hyperthyroidism of long duration should always arouse a suspicion of latent or beginning heart failure. In the accompanying table, we have indicated the average of the two highest metabolism readings, as the circulation time tests were not always done on admission. In many instances, they were not performed until after the patient had begun preoperative iodine medication. Cholesterol determinations are also shown for comparison. In the accompanying graph, correlation points have been plotted indicating the circulation time and basal metabolic rate. It will be noted that the values for circulation time and basal metabolism follow a definite trend and that the distribution of the majority does not depart widely from the mean. It would appear on the basis of this evidence that a shortening of the circulation time is characteristic of hyperthyroidism, and that there is a definite relation between the rapidity of the blood flow and the height of the metabolism in this disease.

We have also demonstrated to our satisfaction, although we cannot present the evidence here, that conditions other than hyperthyroidism which give an increased rate of metabolism are associated with normal circulation time. In following some of our thyrotoxic patients after operation, a return to normal of the circulation time has been observed. In two cases, mild myxedema developed some months after operation, and the blood flow became correspondingly slowed.

Patient 20 was admitted, having received iodine medication before coming to the hospital. Basal metabolic rate on the following day was plus 9 per cent. A circulation time reading of 7.4 seconds strongly supported the original diagnosis of hyperthyroidism. Any doubt as to the correct diagnosis was dispelled by the rising metabolism after iodine had been temporarily discontinued, by the development of a postoperative thyrotoxic crisis, and subsequent histologic study of the thyroid gland.

SUMMARY

The calcium gluconate method of determining circulation time was employed in 72 patients with hyperthyroidism. The average rate was found to be 8.8 ± 0.9 seconds, as contrasted with an average reading of 12.5 ± 1.0 seconds in 60 normal subjects. Evidence is presented to indicate that the circulation time test is useful in the diagnosis of hyperthyroidism. The test is accurate, simple to perform, and entirely safe, as indicated by an experience of more than 500 patients with various clinical conditions. It is suggested, furthermore, that a consideration of the circulation time and blood cholesterol in addition to the conventional basal metabolism test affords a more accurate and balanced interpretation of the state of thyroid function than dependence on one method alone.

THERAPEUTIC EXPERIENCES WITH COBRA VENOM^{*}

By DAVID I. MACHT, M.D., Ph.D., Litt.D., F.A.C.P.,
Baltimore, Maryland

INTRODUCTION

THE materia medica of the ancients abounded in preparations taken from the animal world. Primitive physicians believed that the organs, secretions and excretions of all kinds of animals, including man, possessed mysterious medicinal virtues. Such animal preparations therefore figured largely in the materia medica not only of the Egyptian, Assyrian and Babylonian but also of the Greek and Latin periods and continued to flourish in the pharmacopoeia of the Dark Ages. Even after the Renaissance, at the dawn of modern medicine, the old dispensatories and pharmacopoeias listed a surprisingly large number of "preparations" derived from the animal world. To make them more impressive they were appended to these preparations such Greek, Latin and Hebrew names as appear, for instance, in the Pharmacopoeia Londinensis or New London Dispensatory of William Salmon, Professor of Physick (London, 1702). When the era of modern rational therapeutics and experimental pharmacology had begun, however, most of these preparations were dropped from materia medica but in the past two decades the medicinal use of animal products has been revived to a great extent, largely on account of the developments in the science of endocrinology and the discovery of the vitamins.

Serpents, however, have retained a place of honor in all materia medica from time immemorial. In recent years snake venoms have become the subject of both experimental laboratory and controlled clinical investigation. Their therapeutic uses fall into three distinct categories. One group of venoms, composed mostly of the *Crotalidae* or rattlesnake family, has been used empirically in epilepsy. A second group of snake venoms has been employed in connection with the treatment of blood diseases and used particularly for the control of hemorrhage. In this group are included the American moccasin, *Ancistrodon piscivorus*, the tiger snake, *Notechis scutatus*, and the tropical serpent, *Viper russellii*. But by far the most interesting group from the standpoint of pharmacology and therapeutics is the venoms of the cobras. These have received the greater amount of experimental scientific attention and their therapeutic applications are also of major importance.

It is interesting to note that in the year 1929 an American physician, the former Adolph Monaesler of New York City, gave the first impetus to the study of cobra venom. This wealthy physician, who traveled extensively,

^{*} Read before the annual meeting of the American Therapeutic Society in Atlantic City, N. J., June 4, 1937.

became interested in the curious case of a Cuban leper who, instead of succumbing to the bite of a poisonous tropical spider, was relieved of the excruciating pains in his arm from which he had long been a sufferer. This observation suggested to Monaeslesser the possibility that some animal poisons might serve as pain-relieving agents and he communicated his thoughts on this subject to Calmette, distinguished savant of the Pasteur Institute who, far from ridiculing the idea, thought it worth putting to a test. Monaeslesser in collaboration with the French physicians, Oliveira and Dumatias, began an examination of snake poisons. The three physicians finally selected for their special study the venom of the cobra probably because it is richest in those substances to which the name of "neurotoxins" has been applied. These substances, the chemical nature of which is still unknown, exert their poisonous effects on the nervous system. The results the French investigators obtained in their studies with cobra venom read like a fairy tale but cannot be recounted here in detail. Suffice it to say that the scientists of the Pasteur Institute finally reported that injections of small and safe dosages of cobra venom effectively relieved severe pain of chronic character and particularly that of advanced and hopelessly malignant tumors. In concluding these introductory remarks, the writer desires to mention the interesting fact that 800 years ago the famous Hebrew physician and philosopher, Maimonides, the prototype of the physician in Scott's novel, "The Talisman," stated in his medical treatise, *Pirque Moshch* (ed. Vilna, 1914, chap. 9, p. 26) that snake venoms were useful in the treatment of *tza-ra-ath*, or "leprosy," and *sar-ton*, or "cancer."

COBRA VENOM AS AN ANALGESIC

Cobra venom was thus first scientifically employed by scientists of the Pasteur Institute, who found it useful in relieving the severe pains of malignant diseases. A number of well-known names are connected with this work and the literature on the subject has been given by the writer in another paper.¹ Stimulated by the reports, the present author began both laboratory and clinical investigation of the drug. In investigating this subject, the writer's object was fourfold: he wished (1) to study the pharmacology and toxicology of cobra venom according to the latest technical methods, (2) to prepare and assay biologically a sterile and safe solution of cobra venom for therapeutic use in human patients, (3) to ascertain in carefully controlled studies how effectively cobra venom alleviates the severe pain of patients with malignant tumors, and (4) to analyze the pharmacodynamic mechanism by which the drug produces analgesia or relief of pain, as described by previous writers.

The author performed most of his experiments with the venom of the Indian cobra, *Naja tripudians*, sent him in the form of dried scales by a colleague in India. Additional experiments were made with the venom of the African cobra, *Naja haji*, obtained from another colleague in Egypt. It

may be stated at once that the venom from both species acted in the same way. In connection with clinical studies of cobra venom it was very difficult at first to devise a method by which solutions of the drug could be absolutely sterilized from both aerobic and anaerobic organisms. Inasmuch as most snake venoms are easily destroyed by high temperatures and soon commence to deteriorate even at room temperature, special methods had to be employed in making the solution of cobra venom. Finally, however, there was developed in our laboratory a technic whereby a safe solution of the drug can be prepared.

The writer has devoted considerable study to the mechanism of the analgesia produced by cobra venom, a subject which he discussed in a previous paper and which had heretofore received little attention.² Some think that because that member of a human victim which has been struck by the fang of the cobra becomes numb and paralyzed, the venom produces a local anesthetic action. This is true when an enormous quantity of venom is injected at one place. Such a numbness, however, is in reality a manifestation of protoplasmic poison and not, in the strictly pharmacological sense, an evidence of the local anesthetic effect produced on the peripheral nervous structures. The writer has definitely established by his experiments that such minute quantities of cobra venom as have been employed therapeutically in very dilute concentrations, produce no demonstrable local anesthetic action either on the sensory or motor nerve endings or on the nerve fibers of the ascending or descending peripheral nervous system. On the contrary, all the writer's physiological or pharmacological data, derived from experiments performed in different ways, point to the pain areas in the cerebrum as the locus of the analgesia produced by injections of cobra venom. Evidence to support this conclusion has been adduced from (1) experiments concerning the antipyretic effect produced by cobra venom, (2) studies on the antagonism displayed by cobra venom for certain drugs producing epileptiform convulsions in animals, (3) experimental psychological study of the behavior of white rats trained in a circular maze, (4) special quantitative studies on pain threshold of guinea pigs and (5) special quantitative studies on pain threshold of human beings according to methods developed by the writer in connection with his study of opium alkaloids.^{3, 4, 5}

The conclusion drawn from the various experiments was that cobra venom, like opium and its principal alkaloid, morphine, relieves pain through its action on the higher centers of the brain. The two drugs exhibited a marked difference, however, with regard to what may be styled the "fourth dimension of pharmacodynamics," namely, the time element involved in all pharmacological action.⁶ It was found that while morphine relieves pain very promptly—that is, that the analgesia it produces is rapid in onset—the effect of the alkaloid wears off within a few hours. Cobra venom, on the contrary, does not induce analgesia rapidly. It is usually necessary to give an injection of the drug on each of several successive days before the analgesic action is fully developed. The analgesia effected by this drug, how-

ever, once it is induced, lasts much longer than that of morphine. In a separate paper the writer has described biochemical experiments which revealed that morphine is rapidly oxidized by fresh brain tissue *in vitro* and by the oxidative processes of the brain *in vivo*, whereas cobra venom remains unchanged in the brain tissue of animals injected therewith for a much longer time⁷ and its therapeutic action is therefore of longer duration.

CLINICAL EXPERIENCES

The usual dosage of cobra venom recommended by the writer is five mouse units. A mouse unit is the quantity of cobra venom solution required to kill a white mouse weighing 22 grams within 18 hours after its intraperitoneal injection with the drug. Foreign investigators have employed much larger doses,⁸ but the writer deems it wiser to begin with small therapeutic doses and to study each clinical case carefully before the optimum dosage for the individual patient is established. Five mouse units is a dose below the average and certainly quite innocuous. Cobra venom is not as poisonous as some well known alkaloids and even less toxic than the glucoside ouabain, which is generally regarded as but a heart stimulant.⁹ Of course, there is no difference between drug and poison. Every drug may under certain conditions become a poison and, *vice versa*, almost every poison may occasionally become a useful medicinal agent. It is the writer's usual procedure to first inject but one half the contents of an ampule, or 2½ mouse units. On the following day, a whole cubic centimeter (5 mouse units) is injected. Similar doses of 5 mouse units each are injected for several successive days until a definite analgesia is noted or a contraindication for the use of the drug is encountered. In the writer's experience the latter sequel is very rare. Once analgesia has been established, patients may usually be kept comfortable with two or three injections of 5 mouse units each a week. The writer has personally administered two such injections twice a week to patients with advanced and hopelessly malignant cancers for months in succession and been able to keep them comfortable by using no other drug than cobra venom.

The injections are given intramuscularly. Local reactions have been unimportant.

In the subjoined table are classified the pathological conditions in which cobra venom has been employed by various physicians in collaboration with the writer. He is especially grateful for the cooperation of Dr. Curtis F. Burnam of the Howard A. Kelly Hospital, who was one of the first and most interested collaborators in the work, and also for the continued interest of the late Dr. Joseph Colt Bloodgood of the Johns Hopkins Hospital in this connection. The clinical studies reported here have been carried on for several years and the writer is unable to name the numerous colleagues who have so kindly reported their experiences to him.

TABLE SHOWING CLASSIFICATION OF CASES

| | | | | | |
|----------------------------------|----|--------------------------|---|----------------------|-----|
| Cancer of breast | 20 | Cancer of ovaries | 4 | Cancer of stomach | 2 |
| Cancer of uterus | 35 | Cancer of tongue | 5 | Cancer of orbit | 1 |
| Cancer of rectum | 13 | Cancer of floor of mouth | 3 | Myxolipoma | 1 |
| Cancer of jaw | 13 | Cancer of primary glands | 5 | Intestinal adhesions | 1 |
| Cancer of bladder | 7 | Cancer of prostate | 5 | Pyelocystitis | 1 |
| Cancer of retroperitoneal tissue | 6 | Cancer of penis | 1 | Raynaud's disease | 1 |
| Cancer of lungs and mediastinum | 6 | Cancer of spine | 5 | Angina pectoris | 2 |
| Tumor of bone | 5 | Cancer of thyroid | 2 | Arthritis | 10 |
| Epithelioma | 4 | Cancer of tonsils | 2 | Tic douloureux | 6 |
| Cancer of Fallopian tubes | 1 | Cancer of antrum | 1 | Other neuralgias | 10 |
| | | Cancer of larynx | 1 | Morphinism | 3 |
| | | Cancer of intestines | 3 | Parkinson's disease | 15 |
| Total number of cases studied | | | | | 200 |

Of the 185 cases enumerated in the table (15 cases will be discussed separately), 70 per cent showed definite relief of pain and in 10 per cent more of the cases some slight relief of pain was manifested. Twenty per cent of the total number either experienced no relief at all or were doubtful. One half the 70 per cent of patients that were definitely relieved showed marked improvement in their general condition and could dispense with other medication. The series of cases reported here is larger than that discussed for the first time before the National Academy of Sciences, and the therapeutic results obtained agree admirably with those described by Professor Saenz of the Pasteur Institute, who wrote the author as follows:

Monsieur et Cher Confrere. En ce qui concerne le traitement du cancer par le venin de cobra, un fait est desormais acquis: il a une reelle action anesthesiante dans 70 pour cent des cas traites. Nous ne pouvons pas dire le même chose au sujet de son action curative car malheureusement les cas studies sont peu nombreux et ne permettent jusqu'a present d'aucune conclusion.

It will be noted that Professor Saenz claimed that 70 per cent of his cases experienced relief or "anesthesia" and that he adds that cobra venom is but a symptomatic therapeutic agent and not a curative drug although studies on the effects of venoms on experimental tumors in lower animals are in progress in European laboratories.

Similar experiences have been described by Kirschen,¹⁰ who summarizes his findings as follows:

Cobra venom injections were given 23 patients suffering from inoperable and incurable carcinoma of the gastrointestinal organs. There were 15 stomach cases, three lung cases, three intestinal cases and two breast carcinomata. The effect of treatment in most cases was to reduce pain and improve the general condition of the patient. Improvement in general condition and increase in strength were ascribed to control of pain. Morphine was reduced to a minimum and appetite was restored so that patients could take nourishment, in that way their wasting was checked. The analgesia, followed by no narcotic by-effect or mental depression, undoubtedly exerted a favorable psychological influence on the patients. The author states in conclusion that he would dislike to miss a single opportunity to use cobra venom in the treatment of inoperable and recurrent cancer and agrees with Korbler with regard to the therapeutic results obtained with this drug.

It would require too much space to describe in detail here all the cases which have been collected by the writer or to note the impressions concerning cobra venom treatment sent in by various physicians, but a few citations on this subject may be appropriate. The following interesting account is taken from a letter written by a colleague in the middle West who was originally very skeptical regarding the analgesic virtues of cobra venom.

Patient has been in a hospital for far-advanced cancer patients for one year—carcinoma of the cervix with recto-vaginal fistula. She has had considerable pain about the rectum which was not relieved by an alcohol intraspinal injection done several months ago. We had given her narcotics twice to the point of addiction, then took her off them. But they had soon again to be given in increasing quantities. Just before March 6, 1937, she received morphine ($\frac{1}{2}$ gr) and dilaudid ($\frac{1}{16}$ gr) every two hours, and she was quite nervous, irascible and hard to handle. For several months her appetite was poor and all her vegetables and other food had to be strained twice before she would touch them. Though she had rectal incontinence, she seemed constipated and her abdomen was tense.

Snake venom was started March 6. One half an ampule was given the first day and then one ampule a day for five days, after that the drug was given every other day until she had had six more injections. Not much effect was noticed until about five injections had been given but since then she has been a different person. The narcotics were gradually lessened so that now she receives a grain or $\frac{1}{2}$ grain of codein at night and nothing else. She has had no snake venom injections for six days now. Her appetite has improved, so that now she eats anything and the nurses, and the director in charge, asked me to express to you their gratitude especially because they do not have to laboriously prepare all her food.

The subjoined lines from a resident physician of an eastern hospital indicate the efficacy of cobra venom solution in relieving pain caused by bone affections.

You will recall that some time ago you sent me 10 ampules (5 mouse units) of cobra venom with the request that I use it as an analgesic in cases of intractable pain. Thus far, I have been unable to use it on cases of coronary thrombosis, as you suggested, but have succeeded in prevailing upon our surgeon-in-chief to permit me to use it in the case of one of our graduate nurses who has an adamantinoma of the jaw with secondary staphylococcal infection, producing an osteomyelitis. In her case opiates (morphia, pantopon, dilaudid, etc.) had very little, if any, effect in alleviating the severe pain accompanying her condition, and it was because of this that Dr. ——— permitted the house staff to use the cobra venom. Our results with it have been nothing less than remarkable, and I feel that you should know about them.

After a preliminary dose of 25 mouse units, she received 5 units daily for two days. At the end of this time she became rather stuporous, so that cobra venom was discontinued for three days. Then it was begun again in doses of 25 mouse units (0.5 cc), and she has been receiving this dosage every two days. It has relieved her pain almost entirely, and for the first time in her clinical course of almost a year here at the hospital, she has had sedation and rest. No narcotics have been given in conjunction with the cobra venom. At night she receives nembutal, from 15 to 30 grains, and this has been sufficient recently to induce sound sleep.

Again, a physician on the Pacific coast, who has used many ampules of cobra venom solution, states that the drug has proved highly satisfactory in the treatment of cancer cases suffering much pain.

In cancer patients the relief has been highly satisfactory, and the injections have not apparently been required oftener than every two to four days, an average of about three days

In severe arthritis—chronic hypertrophic and atrophic—the results have been fully as good as “one could expect” In all persons there was surcease from mental depression, which relief lasted from two to five or six days

The following excerpt is taken from the letter of a Canadian physician who treated a confrere for advanced carcinoma of the rectum This case was remarkable in that the patient survived for many months, kept comfortable by regular injections of cobra venom solution

We are pleased to advise you as to the progress of the case of Dr S—— Prior to the injection of cobra venom he was receiving as much as 4 H M C's number one with quarter grain of morphia added at times He received the first ampule of cobra venom February 19 with no untoward effects noted This was repeated the following day and again on the 21st During the first few days we had to resort to narcotics only occasionally By the third day his relief from pain was almost absolute Since his third injection there has been complete and lasting disappearance of his previously excruciating pain It was observed that for a few days following the third injection he lost his sense of taste, this, however, has returned

The subjoined report concerns one of the unfortunate sequelae of radiation treatment in cases of malignant disease This patient had a cancer of the roof of the mouth and was vigorously treated with radium, which caused complete disappearance of the malignant tumor but resulted in a persistent and extremely painful ulcer on the same surface The patient's son, himself a physician, describes the results of cobra venom therapy as follows

May I begin by saying that I can never thank you enough for the cobra venom you sent me for my father I would have reported my results to you before this had not my father's condition been very poor for some time following the sudden death of my mother However, at the present writing he is almost his old self again He was in my office today, having driven himself in from the country, a distance of about 16 miles (incidentally, to have a plate adjusted by the dentist) His condition had so markedly improved after the first 11 injections of cobra venom that when he received in addition two more doses from the last lot you sent, all pain subsided and I saw no need to give him any more The ulcer in the roof of his mouth has completely healed but has left an opening through the hard palate Practically all tenderness has vanished so that he can wear a plate made to cover the opening with much comfort There are no signs of any malignancy and I feel that he has almost completely recovered, anyway, his improvement appears to continue

While cobra venom was chiefly advocated in cases of hopelessly advanced malignant tumors and their metastases, the writer during the past year or two has become interested in extending its use to the treatment of certain non-malignant conditions Included among these are severe neuralgias like tic douloureux, cases of chronic arthritis which could not be relieved except by narcotics, and cases of angina pectoris with subacute, long-lasting paroxysms of pain The number of arthritis cases treated with this drug is

still not large enough to warrant discussion although considerable relief of pain has been obtained in some instances

Finally, the writer wishes to add a word as to a new indication for therapy with cobra venom. While he was studying a series of chronic arthritis cases and endeavoring to relieve their sufferings with various non-narcotic drugs, two patients afflicted with advanced Parkinson's disease with contractures and severe arthritic pains came under his observation through the courtesy of a colleague. It was deemed advisable to try the effect of cobra venom (in place of a host of antipyretics and codeine, to which they had become accustomed) on these two patients. To the surprise of attending physicians, cobra venom not only relieved the pain but also relaxed the rigidity of the muscles and produced a general amelioration of the patients' symptoms. This finding prompted a search for cases of Parkinson's disease, particularly those with marked pain and rigidity. Fifteen such cases have already been studied and it may be stated that the spasticity and pain of half that number have been definitely relieved. The number of cases thus treated is still too small to warrant any general conclusion but certainly stimulates further study on the subject.*

The *modus operandi* of the drug in such cases is probably a complex one. (1) The analgesic action of cobra venom certainly plays a rôle, (2) the anticonvulsant property of the drug may play a rôle, and (3) it is quite probable that certain peripheral effects of cobra venom described by Ciccardo¹¹ may also be involved in the mechanism of the drug's action.

It is well to call attention to the fact that practically all the cases tabulated above had been treated, prior to administration of cobra venom, with all kinds of drugs including such narcotics as morphine, codeine, pantopon and dilaudid and in many cases had also been subjected to radiation with roentgen-rays and with radium. Very often cobra venom was used as a last resort when all the other therapeutic measures had failed, and it is gratifying to be able to state that in most of such cases the narcotics and other analgesic drugs were gradually reduced in dosage and finally dispensed with altogether after initiation of the cobra venom treatment.

The question of addiction arising at this point in his discussion, the writer wishes to state that up to the present time no signs of addiction, in the narcotic sense of the word, have been noted after as much as a year's treatment with cobra venom. Some physicians, however, have reported that their patients' mental attitude in general had been favorably affected by the drug. Whether this effect of cobra venom therapy is a true euphoria or merely the result of relief from pain and improvement in general condition

* Since the manuscript of this paper was sent the editor, the use of cobra venom in Parkinson's disease has been further investigated by the writer and other physicians. Such studies have confirmed the original findings concerning effectiveness of the drug in relieving symptoms of the Parkinsonian syndrome. The most important work done in this direction has been reported by Drs. Gavle and Williams in the February issue of the Southern Medical Journal, 1938.

of the patient cannot be definitely asserted. In the series he has studied only three cases of true morphine addiction have been brought to the writer's attention. One of these, a physician who suffered from neuritis, became an addict to morphine and dilaudid and came to a Baltimore hospital for treatment. Without the patient's knowledge, the dosage of the opiate was gradually decreased and cobra venom injections were substituted for such therapy. Finally the patient was taken off narcotics altogether and kept comfortable with the cobra venom injections. An out-of-town physician has reported that he has successfully treated two morphine addicts by combining injections of cobra venom with those of insulin. The drug has so far been found to produce no such symptom as morphine or other opiates or cocaine effects. In some cases it has been found to produce a general stimulation and improvement of the patients' psyche probably through relief of pain.

SUMMARY

The venom of the deadly cobra, in sufficiently small doses and in sterile solution, has been found to be an efficient therapeutic agent for the relief of pain, particularly that of advanced malignant disease. Its use is being extended to the treatment of certain chronic non-malignant diseases accompanied by a great deal of pain. This drug, which is no more poisonous than many of the alkaloids and glucosides officially recognized by the medical profession, has been successfully used to displace analgesic drugs of the coal-tar and narcotic types. Like morphine, it depresses pain areas in the cerebrum but it differs from morphine in that its analgesia is slower in onset and longer in duration than that effected by the alkaloid. Modern pharmacology and therapeutics have thus restored the old empirical use of snake venoms described by the ancients to a place in the armamentarium of the progressive physician of today.

GASTRIC SECRETION IN CASES OF PERNICIOUS ANEMIA *

By HENDRIK M. ROZENDAAL, M D , *Schenectady, New York*, and
RICHARD N. WASHBURN, M D , *Rochester, Minnesota*

MANY authors believe that achlorhydria is a constant finding in cases of pernicious anemia. There are, however, a number of reported cases of pernicious anemia in which free hydrochloric acid was present in the gastric contents. Alsted was able to collect 32 such cases from the literature.

The cause of the achlorhydria in these cases is unknown. Faber was of the opinion that achlorhydria is always the result of atrophic gastritis which, according to him, is a constant finding in cases of pernicious anemia. Hurst, on the other hand, emphasized the constitutional factor in achlorhydria. The frequent familial occurrence of achlorhydria and of pernicious anemia, together with Conner's observation that achlorhydria has a distinct tendency to occur frequently among blood relatives of patients who have pernicious anemia, supports this view. It was Hurst's opinion that the absence of free hydrochloric acid predisposes to the development of inflammation of the mucous membrane.

There has been much evidence produced to prove that achlorhydria usually, if not always, precedes the onset of the anemia by a considerable time. Riley, Conner, Strandell, Levine and Ladd, Hurst, Faber and Gram, and Sturtevant have reported cases in which achlorhydria was found from one to several years prior to the onset of symptoms of pernicious anemia. In Strandell's series of 20 cases there was only one case in which free hydrochloric acid was found to be present before the development of pernicious anemia.

We have reviewed the records of 906 consecutive cases from the files of The Mayo Clinic, in which a definite diagnosis of pernicious anemia was made. Achlorhydria was found in all of the cases. This finding corresponds with the recent report of Sturgis on 600 cases of pernicious anemia. In none of our cases was there a return of free hydrochloric acid following treatment for the anemia. This finding is in contrast with that of Hurst, who has observed four cases of pernicious anemia in which the secretion of free hydrochloric acid returned following treatment of the gastritis. However, treatment for gastritis was not instituted in any of the cases we reviewed. Jones, Benedict and Hampton have demonstrated improvement in the appearance of the gastric mucous membrane during treatment of pernicious anemia.

In 36 of the cases a study of the gastric secretion was made from two to 21 years prior to the onset of symptoms of pernicious anemia. In the majority of these cases the concentration of hemoglobin was determined.

* Submitted for publication May 10, 1937

and a blood count was made at the time of the first examination. The findings are recorded in table 1. Those cases in which an analysis of the gastric contents was made in the two years before the first appearance of

TABLE I
Clinical Findings in Cases of Pernicious Anemia

| Case | Age of Patient at Time of First Examination, Years | Sex | Percentage of Hemoglobin (Dare) | Corpuscles per Cubic Millimeter of Blood | | Free HCl in Gastric Contents (Method of Topfer) | Years Which Elapsed Between Original Examination and Development of Symptoms of Pernicious Anemia |

symptoms of pernicious anemia were purposely excluded. In the last column of table 1 is recorded the number of years which elapsed between the first examination of the gastric contents and the onset of symptoms of

pernicious anemia Only cases in which a clear-cut history of the onset of pernicious anemia could be obtained are included

From a study of these cases it appears that in 34 cases achlorhydria was present from two to 21 years before the first symptoms of pernicious anemia developed, and in two cases (cases 32 and 35) free hydrochloric acid could be demonstrated 19 and 17 years, respectively, prior to the onset of pernicious anemia

The average age of the patients at the time of the original examination was 48 years According to the figures of Vanzant, Alvarez, Eusterman, Dunn, and Berkson, about 18 per cent of normal individuals of a corresponding age group have achlorhydria

It appears from these observations that achlorhydria almost always can be found a number of years prior to the development of the first symptoms of pernicious anemia, and we are in complete agreement with the statement made by Strandell, namely, that achylia in pernicious anemia is not a symptom due to the anemia but a factor of a far more deep-seated character

It is noteworthy that in this group there are only two cases with achlorhydria (cases 26 and 28) in which microcytic hypochromic anemia was present prior to the development of pernicious anemia In the remaining 34 cases the values for hemoglobin and the number of erythrocytes varied within the normal range at the time of the original analysis of the gastric contents

A relationship between simple achlorhydric anemia and pernicious anemia has been suggested by the finding of achlorhydria in the two diseases Heath, for instance, has reported a family in which some members suffered from hypochromic anemia whereas others had typical symptoms of pernicious anemia Cases in which a transition of simple achlorhydric anemia into pernicious anemia occurred have been reported by Witts, Faber and Gram and others Faber and Gram said that "there is such a close relationship between these two diseases that we have grounds for assuming a very intimate pathogenetic connection" It seems to us that the occasional occurrence of these two diseases can be explained on the basis of coincidence, and the fact that in the present group of cases only two such instances could be found makes us believe that the two diseases form definite clinical entities

SUMMARY

Achlorhydria was a constant finding in a series of 906 cases of pernicious anemia In 36 cases analysis of the gastric contents was performed from two to 21 years prior to the onset of symptoms of pernicious anemia In 34 of these cases achlorhydria was found In two cases free hydrochloric acid could be demonstrated 19 and 17 years before symptoms of pernicious anemia developed In only two cases was a hypochromic anemia found at the time of the original examination We believe that pernicious anemia and simple achlorhydric anemia are separate clinical entities

URTICARIA—A NEW THERAPEUTIC APPROACH ~

By HOWARD A. RUSK, M D , F A C P , and BRUCE D. KENAMORE, M D ,
St. Louis, Missouri

URTICARIA is a localized and circumscribed edema of the skin due to contraction and distorted osmotic balance in the superficial capillaries of the cutis. It has long been considered to be an allergic manifestation, but anyone who has dealt with chronic urticaria has encountered the refractive cases which in spite of all types of allergic withdrawals and desensitizations, will respond to no therapeutic measure. A number of cases are reported in the literature that have continued for many years without relief. Evaluating the allergic factor in the problem is unusually difficult, as this type of case gives the poorest response and is most inaccurate as far as skin tests are concerned, group diets, leukopenic indices, and patch tests are often of no avail. It has seemed to us that this problem of altered vessel permeability, plus a localized edema, could be approached, as in the treatment of other types of edema, from the purely chemical point of view. This, of course, has been done for many years with the use of ammonium chloride, hydrochloric acid, etc., but with the recent work on the sodium-potassium relationship in edema, it occurred to us that this might be an effective therapeutic approach. A review of the recent literature on potassium metabolism and the results obtained in a small series of patients have seemed to bear out this assumption.

The proportion of inorganic salts in blood serum is sodium 100, potassium 6.1, calcium 2.7, and magnesium 0.8. Normal serum contains from 320 to 350 mg. per cent of sodium and 18 to 22 mg. per cent of potassium. Many experiments have shown that deficiency of potassium induced in growing animals causes a definite stunting and if long continued results in death. Feng¹ reproduced Adrian's experiment and showed that the skin-muscle preparation of the frog, when scraped, loses its tactile excitability. He was able to prove that this loss was due to liberation of potassium from the cells of the skin, if the potassium was washed away the skin irritability returned. He was then able to show that application of potassium to an uninjured skin preparation had the same depressing effect on excitability. Duhre and Horton² have also demonstrated that potassium ions have the same depressant effect on muscle excitability. That is to say, when a skin-muscle preparation is irritated nature pours out an excessive amount of potassium to ease the local irritability, and the same effect may be produced artificially by application of potassium to an isolated segment. Nathan and Stern³ in their studies of calcium and potassium content of serum in patients with various types of skin disease found that in the acute dermatoses the potassium fell to a subnormal level, and returned to normal as the skin lesions im-

From the Medical Service, St. Luke's Hospital, St. Louis, Missouri.

proved Mathison⁴ showed that intravenous injection of potassium caused a primary fall in the blood pressure with a secondary rise, and that intra-arterial injection caused a marked primary rise. McGuigan and Higgins,⁵ repeating his experiment, found that potassium had the same action when injected by either route if preceded by epinephrin. Epinephrin increased the potassium in the blood serum, it caused vaso-constriction, contraction of smooth muscle, and cardiac depression. The site of action is directly on the peripheral arterial musculature, and an increase in serum potassium is necessary before the hypertensive effect is obtained. Many other investigators have shown that potassium produces a rise in blood pressure. D'Silva,⁶ and also Schwartz⁷ have noted that epinephrin causes an increase in the serum potassium. Camp and Higgins⁸ have definitely shown that potassium has two actions on the heart: first, vagus stimulation, and second, an increase in ventricular irritability identical with that due to epinephrin. All of the potassium salts apparently cause this effect except potassium permanganate. The potassium threshold is always increased by epinephrin. Schwartz found an increase of 86 per cent in serum calcium following epinephrin. In all experiments potassium and epinephrin acted identically on the heart, intestines, bronchioles, kidneys, etc. One function of the adrenal gland is to maintain a constant potassium content of tissue, and when the epinephrin secretion stops, potassium accumulates in the tissue. Effects attributed to epinephrin are *actually* the effects produced by potassium migration which epinephrin causes. Camp and Higgins, in their explanation of the adrenalin reaction are quoted as follows: "Changes effected by adrenalin are actually produced by potassium. Adrenalin causes an increase in serum potassium. Potassium salts injected intravenously effect changes identical with those produced by adrenalin. This is true not only for the cardiovascular system but for the intestine, bladder, etc. This effect occurs after the removal of the adrenals. Potassium also produces fleeting hyperglycemia, but if potassium is present in large amounts the blood sugar is low."

Klauder and Brown,⁹ in their work on the calcium-potassium ratio and the alteration of cutaneous irritability in rabbits have shown that there is a direct relationship between the degree of irritability and the amount of serum potassium. When the serum potassium was increased, the irritability of the skin was increased. *This is directly compatible with Feng's original experiment, that is, when the serum potassium is high it is because the utilizable potassium has been taken into the serum at the expense of the skin, and the skin irritability, therefore, is increased because it lacks the high potassium content in the cutaneous tissue which decreases its irritability.*

Many investigations have shown that there is a release of histamine in the skin in urticaria. Alexander,¹⁰ and others have noted that if a given area is repeatedly stimulated eventually there will be no response to the histamine stimulation. This can be accounted for on the basis of Feng's work as follows. After repeated stimulation potassium is mobilized in the

given area and the irritability is finally suppressed by the increase in the skin potassium in this area

Because of these basic facts it seems logical, therefore, that potassium should be a valuable drug in the treatment of edematous lesions of the skin for two reasons: first it lowers the skin irritability directly, and secondly, its pharmacological reaction is very similar to and definitely allied with epinephrin

Results in the small series of patients that we are reporting are far from conclusive, but definitely indicate the therapeutic response. All of these patients had been tried on the various allergic regimes and orthodox treatment without success.

CASE REPORTS

Case 1 D. J., white, male, aged 42. History of recurrent attacks of urticaria for 13 years. Physical examination and laboratory studies were negative. Skin tests were negative. Rowe diets gave no relief. Calcium lactate, nitrohydrochloric acid and ephedrin compounds were not helpful. On April 28, 1936, he was put on a high protein, low sodium, acid-ash diet with ammonium chloride, 45 gr daily, and potassium chloride 60 gr daily. In 24 hours the hives had cleared entirely and he has remained free ever since. He remained on a strict diet for eight weeks when citrus fruits were added. Discharged 15 weeks after institution of treatment on regular diet, entirely recovered.

Case 2 R. B., white, male, aged 57. Recurring urticaria of 10 years' duration. Skin tests were negative. Had had no relief from all types of allergic diets, acid regimes, ephedrin, etc. Had noticed on many occasions recurrent urticaria after taking milk of magnesia (this alkali apparently altering the calcium-potassium ratio). On the outlined regime he has had only an occasional hive and states that his skin has been better than for the previous 10 years.

Case 3 N. M., white, female, aged 60. Urticaria of four months' duration, no allergic history except migraine in mother's family. General physical examination and laboratory work were entirely negative. Various group diets were tried for four weeks without relief. Large doses of nitrohydrochloric acid and ammonium chloride caused little change. Skin tests showed a number of three and four plus reactions, but the removal of these offending foods made no change in the course of the urticaria. On April 7, 1936, patient was put on a low salt regime and nitrohydrochloric acid continued. Her next visit was five weeks later when she stated she was greatly improved but still having an occasional lesion. At this time she was put on a high protein, low sodium, acid-ash diet with 90 gr of potassium chloride daily and has remained comparatively symptom-free since that time.

Case 4 R. L., white, female, aged 40. Has had hives all her life, severe for two and a half years. Has been under the care of a number of dermatologists and has taken vaccines, cleared up foci of infection and taken various types of diet without relief. Skin tests were inaccurate because of a general dermatographia. This patient had a mild secondary anemia and a mild hypochlorhydria. She was put on a high protein, low sodium, acid-ash diet and the following is an excerpt from a letter written four weeks after leaving the hospital:

"I have made a decided improvement. Feeling generally better for longer than I can remember. I still have slight itching. Last night I ate soup with a tiny bit of salt. I had hives at 10 o'clock. Had some recurrence when I ran out of the potassium chloride."

Case 5 B S, white, female, aged 18 Chronic urticaria, recurrent for two years and a loss of 25 pounds in weight Recurrence of hives whenever she had a cold Various types of diet gave no relief No history of allergy in family Physical examination and laboratory work were entirely negative Was put directly on a high protein, low sodium, acid-ash diet with added vitamin D and 60 gr of potassium chloride daily Four days later she had very few hives and at the end of 15 days the hives had cleared entirely Skin has remained clear except for an occasional dietary indiscretion When last seen she was taking a fairly full general diet with simply a low sodium content

Case 6 N F, white, female (through courtesy of Dr Francis E Sultzman) This patient was an obese, mildly hypertensive, hypopituitary type of individual who had been on a low caloric diet for weight reduction In November 1936, she developed a severe urticaria After this had been present for one month she was put on a high protein, low sodium, acid-ash diet and the urticaria cleared up promptly, until at the end of 10 days she was entirely free from all signs and symptoms There has never been any recurrence She has remained on alternating low caloric, low sodium, acid-ash diet alternating at two week intervals with regular diet

This series of patients was observed from a purely clinical standpoint, laboratory facilities were not available for the many chemical determinations necessary to make the study complete However, all of the patients responded clinically in a manner that was most gratifying The high protein, low sodium, acid-ash diet with added potassium chloride as outlined by Baiker¹¹ for the relief of cardiovascular edema, and as recommended by Rusk and Newman¹² in the treatment of portal cirrhosis with ascites was devised to maintain a constant mild diuresis This is accomplished by mild tubular irritation which the potassium produces and by the additional fluid loss which an acid-ash residue causes Proteins, non-citrus fruits, and certain vegetables catabolize to such a residue From this regime there results a shift in the mineral balance of the tissue fluids, with an increase in the potassium constituents at the expense of the sodium We have employed this diet, which follows below, in two forms one a well balanced menu of normal caloric value for those in average nutritional states, the other, of low caloric (1050 cals) figures for those patients who are obese

HIGH PROTEIN, LOW SODIUM, ACID-ASH DIET OF AVERAGE CALORIC VALUE

FRUITS

3 servings daily, fresh or stewed, but should include either prunes, plums, cranberries, or currants once daily

VEGETABLES

2 large servings daily, especially beets, carrots, brussels sprouts, yellow corn, kohlrabi, lettuce, mushrooms, peas, spinach, kidney beans, parsnips

MEAT

2 servings daily

EGGS

2

MILK

1 glass

CREAM

½ glass

BUTTER

Salt-free, 6 squares

CEREAL

Oatmeal or wheatena, Farina, puffed wheat or rice occasionally

BREAD

Graham bread, 3 large slices or 6 small slices daily

RICE, MACARONI OR SPAGHETTI

1 serving daily

POTATO

1 serving

JELLY, PRESERVES OR HONEY

2 level tablespoons

SUGAR

Ad libitum—at least 1 tablespoonful

NOTES

All foods are to be prepared without salt and no salt is to be served with meals
 Potassium chloride (from 2 to 5 gm in shaker) may be given as salt substitute
 Spices—cinnamon, sage, paprika, pepper, cloves, nutmeg, allspice may be used
 Small servings of citrus fruits may be added after fluid volume is established
 Additional vitamin D to be supplied

Coffee or tea, 1 cup daily

HIGH PROTEIN, LOW SODIUM, ACID-ASH DIET OF LOW CALORIC VALUE
 (APPROXIMATELY 1050 CALORIES)

BREAKFAST

1 serving of 10 per cent fruit

2 eggs

1 slice whole wheat bread $3\frac{1}{2}$ by $2\frac{5}{8}$ by $\frac{1}{2}$ "

Coffee with saccharin and 2 tablespoons skimmed milk if desired

LUNCH

Veal cutlet one piece 6" by 4" by $\frac{1}{2}$ ", or

2 veal chops, or

Lean round steak one piece 4" by 3" by $\frac{3}{4}$ ", or $\frac{2}{3}$ cup ground lean beef, or $\frac{2}{3}$ cup sweetbreads, orCalf liver $4\frac{1}{2}$ slices 2" by 3" by $\frac{1}{4}$ ", or

3 pair frog legs—large, or

 $1\frac{1}{2}$ pieces fish 4" by 3" by $\frac{1}{2}$ "

Broil these meats with mineral oil

Vegetables

1 serving of 5 per cent vegetables

Salads

1 Hard cooked egg (1)

2 Cottage Cheese— $\frac{1}{4}$ cup3 Vegetable salad of 5 per cent vegetables If this salad is selected, add $\frac{3}{4}$ cup broth to this meal

Serve salad on 3 lettuce leaves with mineral oil dressing

Make this dressing by using your favorite French or mayonnaise
 recipe, substituting mineral oil for salad or olive oil,
 and potassium chloride for table salt

1 serving of 10 per cent fruit

 $\frac{1}{4}$ cup skimmed milk or skimmed buttermilk

DINNER

- $\frac{3}{4}$ cup broth or jellied broth
- Roast veal, lean beef, chicken, turkey, or lamb $2\frac{1}{2}$ slices
4" by 4" by $\frac{1}{8}$ "
- 1 serving of 5 per cent vegetables
- Vegetable salad of 5 per cent vegetables with 3 lettuce leaves and mineral oil dressing
- 1 serving of 10 per cent fruit
- $\frac{3}{4}$ cup skimmed milk or skimmed buttermilk

DIET INSTRUCTIONS

- 1 Eat nothing that is not on diet list
- 2 Do not use citrus fruit oftener than once daily, best to omit entirely
- 3 Do not use fats in cooking Mineral oil may be used
- 4 Do not use table salt in cooking or on food
- 5 Do not take any alkaline medicine as sodium bicarbonate
- 6 Limit fluid to 7 cups, $\frac{3}{4}$ full, daily, including liquids consumed with meals

The problem of potassium toxicity to which older investigators attach much importance has not been a complication in this series. Only in one patient, an anemic, emaciated individual have we noted muscular pains, vertigo, headache, sweating, and other symptoms of potassium intoxication. These were quickly relieved by a reduction in dosage. Potassium chloride in doses of 60 to 90 grains a day has been a safe drug in our hands, more readily tolerated if enteric coated.

COMMENT

The potassium-sodium-adrenal relationship is already a definitely established clinical entity in Addison's disease¹³. A sound physiologic and pharmacologic basis seems to exist for the treatment of the various allergic phenomena by further change in the already abnormally altered mineral balance. It has been definitely shown from numerous sources that in skin irritability and skin inflammation the potassium metabolism is markedly altered, and that an increase in skin potassium causes an appreciable decrease in localized irritability. It also has been shown definitely and conclusively, that potassium is almost identically adrenal-like in its pharmacological action. Because of these known facts it seems logical that certain allergic problems could be approached from this therapeutic angle with benefit. In a small series of cases of chronic urticaria, a high protein, low sodium, acid-ash diet, with added potassium chloride, has produced promising clinical results. We hope that this small series of cases will stimulate a further trial of what we believe to be a sound and fundamental therapeutic principle.

UPPER LOBE PNEUMONIA IN THE ADULT

By MILTON B. ROSENBLATT, M.D., and ARNOLD BACHMAN, M.D.,
New York, N. Y.

PNEUMONIA of the upper lobes is neither a new nor a rare occurrence. It was described by Laennec and also by his contemporaries, Andral and Broussais. However, despite the common knowledge of its existence there have been exceedingly few references to this subject in the literature. This is equally true of the standard textbooks which deal very extensively with the general subject of pneumonia. It is not difficult to fathom the cause of this apparent neglect. The diagnosis of apical pneumonia by physical signs, alone, is attended with great difficulty and, in the absence of routine roentgenograms, the number of cases diagnosed correctly is very small and has offered little opportunity for clinical study. We have therefore made a detailed analysis of a series of cases of upper lobe pneumonia at the City Hospital with particular emphasis on the differential diagnosis, the course of the illness, and the prognosis. We hope that by calling attention to this type of pneumonic involvement the diagnosis will suggest itself in many obscure pneumonias observed in private practice without physical signs of consolidation.

As was stated above upper lobe pneumonia is by no means a rare occurrence, it is only the diagnosis which is infrequent. In a series of 522 cases of pneumonia Adams¹ found 97 instances (18.5 per cent) of isolated upper lobe involvement. MacCordick,² in a similar series, reported a 26 per cent incidence and Warr and Alperin³ found a 10 per cent incidence. Our study covered a period of 21 months from August 1934 to April 1936. The total number of pneumonia cases admitted to the Second Medical Service was 180 of which 24 (13.3 per cent) had primary upper lobe involvement. There were 20 white patients and 4 colored ones and the sex incidence was 18 males and 6 females. The age groups ranged from the second to the ninth decade but the majority of the cases (70 per cent) were in the third, fourth, and fifth decades.

Three types of onset were noted, namely, acute, catarrhal, and meningitic. The first two groups included the vast majority of patients and consisted of 22 cases. There were but two instances of frank meningitic onset. Of the nine cases whose illness began acutely with chill, fever, and chest pain there were two which subsequently showed meningitic features. The catarrhal group consisted of 13 patients. All began with upper respiratory disease. Four developed pneumonia insidiously, seven had acute symptoms following the catarrhal phase, and two showed meningitic manifestations after the catarrhal period.

* Received for publication October 9, 1936.

From the Second Medical Service of the City Hospital, New York.

The course of the illness in these 24 upper lobe pneumonia patients was carefully analyzed. The degree of toxicity was arbitrarily divided into three grades according to the composite clinical appearance of the patients and it was found that sixteen (66 per cent) of the cases were in Grade III (markedly toxic), four (17 per cent) were in Grade II (moderately toxic), and four (17 per cent) were in Grade I (slightly toxic). The number of patients who required oxygen therapy is also an indication of toxicity inasmuch as the routine requisites for oxygen administration were a heart rate above 135, respirations above 35, or the presence of cyanosis. Eleven patients were given oxygen. The extent and type of pyrexia were also noted. There were 20 patients with temperature above 102° F. Of these 11 were continuously high, seven were remittent, and two were intermittent. There were four patients with temperatures below 102° F, two were continuous and two were remittent.

Study of the lobe involvement of these cases according to roentgen-ray findings revealed 14 instances of single upper lobe pneumonia and 10 instances in combination with either the contra-lateral upper lobe or one of the lower lobes. The number of times each individual lobe was affected was as follows:

| Lobe | Number of Instances Involved |
|-------------------------------|---------------------------------|
| Right upper | 19 |
| Right middle | 1 |
| Right lower | 4 |
| Left upper | 7 |
| Left lower | 6 |
| Right and left upper combined | 2 |

It is of interest that in three of the cases of single upper lobe involvement no physical signs could be detected despite the roentgen demonstration of the lesions. In the cases with multiple lobe involvement the diagnosis of associated lower lobe disease by physical signs checked very closely with the roentgen-ray. The course of illness in the two groups was strikingly different. The 14 cases with single lobe involvement had a mortality rate of 21 per cent whereas the 10 cases with multiple involvement had a mortality rate of 70 per cent.

The duration of illness in the entire group of upper lobe pneumonias varied considerably. Of the 14 cases which survived five recovered by crisis and nine by lysis. The chart below depicts the number of days of illness of each of the patients and the mode of termination of the disease.

The number of cases in our series is not large enough to warrant any generalized conclusions but the above chart definitely shows that most of the patients who died did so within a 10 day period of illness. It also indicates that most of the patients who recovered by lysis were ill for a period greater than 10 days. These facts suggest that in view of the high mor-

DURATION OF ILLNESS AND MODE OF TERMINATION

| | Number of Patients | Individual Duration of Illness (in days) | Average Duration of Illness (in days) |
|----------------------|--------------------|--|---------------------------------------|
| Terminated in Crisis | 5 | 6 6, 6, 9, 9 | 7 2 |
| Terminated in Lysis | 9 | 4, 7, 11, 16, 16, 16, 18, 22, 24 | 14 9 |
| Terminated in Death | 10 | 4, 4, 5, 5, 7, 9, 9, 10, 11, 22 | 8 6 |

ality rate (42 per cent) in this disease a 10 day period of survival may be of some prognostic significance. In considering the condition of the pneumonic lesion in the patients who recovered there was found no instance of unresolved pneumonia in the entire group. The roentgenograms of nine showed complete disappearance of the lesion and the remaining six showed residua such as thickening of the apical and interlobar pleurae or linear fibrosis. There is a strong possibility that if these six cases had been roentgen-rayed again they also would have shown complete absorption of the infiltration. This contention is somewhat strengthened by the fact that most of them had no roentgenograms within a week of discharge. None of the patients who recovered had any physical signs at the time they left the hospital.

Most of the cases were worked up completely from the laboratory standpoint and particular emphasis was given to examination of the sputum for tubercle bacilli. There was no instance in which tubercle bacilli were found. In 20 of the cases the sputum was typed for pneumococci by the Neufeld method. The results were as follows:

| | |
|--|----|
| Number of cases negative Types I-XXXII | 13 |
| Number of cases positive Type I | 3 |
| Number of cases positive Type II | 2 |
| Number of cases positive Type III | 1 |
| Number of cases positive Type XIV | 1 |

There may be some significance in the high percentage of negative typings as this is in marked contrast to the results usually obtained in typing lower lobe pneumonias.

Examination of the urine in 20 cases showed nine instances of albuminuria, three instances of hematuria, two instances of glycosuria (non-diabetic), and one instance of choluria. Seventeen cases had chemical examinations of the blood. Two showed azotemia, two showed hyperglycemia (non-diabetic), and three showed cholemia. Twenty-two patients had blood Wassermanns of which two were positive. One of these recovered with complete resolution. Blood counts were done routinely on admission and when indicated during the course of illness. The figures showed nothing of particular significance. The range of leukocytosis was from 10,000 to 35,000 and the percentage of polymorphonuclear cells varied

from 45 to 95. All cases showed a decided shift to the left by the Schilling count.

No pulmonary complications were observed. However, there were many extra-pulmonary complications which were indicative of the severity of the disease. Five patients showed toxic psychoses, nine had toxic albuminuria, three had focal glomerular nephritis of whom two showed azotemia, three had toxic hepatitis. The severity of apical pneumonia particularly in regard to prostration and cerebral symptoms has been pointed out by Norris and Landis.⁴

The treatment of these cases was chiefly supportive with great emphasis on fluid intake. Oxygen was administered when necessary. One case was given serum. The inability to obtain a specific typing of the sputum in the majority of the cases was responsible for the lack of a more general use of serum therapy.

In discussing the differential diagnosis of apical pneumonia it is of considerable interest that ten (42 per cent) of the cases were diagnosed as pulmonary tuberculosis on admission. The physical signs of many of the cases, particularly those with beginning resolution, were identical with those found in tuberculous lesions. The history of acute onset with chest pain, chill, and fever, when present, was of some diagnostic value but considerable significance was attached to the presence of labial herpes which is rarely, if ever, seen with pulmonary tuberculosis. The roentgen-ray was the most valuable diagnostic aid. While lobar consolidations may occur in tuberculosis they do not undergo complete resolution within a period of two weeks as do those in pneumonia. Putrid lung abscess may resemble apical pneumonia at the onset both clinically and radiographically but the diagnosis is usually established with the expectoration of foul sputum. Meningitis must also be included in the differential diagnosis. Six of our patients showed meningitic symptoms and in two of them spinal punctures were performed because of frank meningitic signs. In these latter two instances there were neither pulmonary symptoms nor signs on admission. In a report of six cases of apical pneumonia Lepage⁵ noted that three of his patients had no cough or expectoration at the onset.

Five of our patients were admitted with the diagnosis of pneumonia based on symptoms alone. No physical signs could be elicited over the affected areas despite their demonstration by roentgen-ray. Two of these cases showed physical signs during the resolution phase but the other three showed no signs on daily examinations throughout the entire period of illness. In these latter instances the diagnosis was made possible only by the roentgenograms. These facts strongly suggest the possibility that the numerous cases observed in private practice in which the patients have the typical history and symptoms of pneumonia but no physical signs are instances of upper lobe involvement.

The clinical syndrome of apical pneumonia with rapid and complete resolution of the lesion is depicted in the following case reports.

CASE REPORTS

Case 1 M H, a 16 year old girl, was admitted on March 12, 1936, with a history of productive cough, evening rise in temperature, and night sweats of two weeks' duration. On physical examination the patient did not appear acutely ill. There

FIG 1 (3-13-36) *Case 1* Pneumonic consolidation of right upper lobe, small infiltration in right middle lobe. Left side negative.

were dullness and diminished breathing over both upper lobes. The temperature ranged between 99° and 102° F. The sputum was negative for tubercle bacilli and for pneumococci types I-XXXII. The admission diagnosis was bilateral upper lobe pulmonary tuberculosis. Pneumonia was considered only as a possibility. Roentgen-ray examination on March 13 showed a pneumonic consolidation of the right upper lobe and a small infiltration in the right middle lobe. The left lung was negative (figure 1). The clinical course was uneventful and the temperature subsided gradually. Daily physical examinations revealed no signs of resolution at any time but

a roentgenogram on March 24 showed complete clearing of the lesion except for a few fibrotic strands extending from the hilum and a thickening of the interlobar pleura (figure 2)

Case 2 L M, a 32 year old woman, was admitted on February 17, 1936, with a history of fever and pain in the right chest of four days' duration. She had noticed progressive loss of weight and weakness for several weeks prior to the onset of the

FIG 2 (3-24-36) *Case 1* Absorption of lesion, residual interlobar pleurisy and hilar fibrosis

present symptoms. Examination on admission revealed the patient to be acutely ill with temperature 104° F. Herpes was present on the upper lip and there were signs of consolidation of the right upper lobe. Roentgen-ray (figure 3) confirmed this. The sputum showed pneumococci type III and was negative for tubercle bacilli. The clinical course was characterized by marked toxicity, high pyrexia, and toxic hepatitis. One week after admission the temperature began to decline and gradual improvement of all symptoms was noted. A roentgenogram on March 3 showed complete resolu-

tion of the pneumonia except for a few hilar strands and thickening of the interlobar pleura (figure 4)

Case 3 J L, a 25 year old man, was admitted on December 1, 1934 with a history of chills and fever of two days' duration His temperature was 104° F Herpes labialis was present The general appearance was that of marked toxicity but the most prominent features were nuchal rigidity, hyperirritability, and delirium

FIG 3 (2-17-36) *Case 2* Pneumonic consolidation of right upper lobe, remainder of lungs negative

which were present to such a degree as to suggest the diagnosis of meningitis Spinal puncture was done and examination of the fluid proved negative Physical examination on admission was inconclusive but a roentgenogram on December 3 showed complete consolidation of the left upper lobe (figure 5) Pneumococcus typing of the sputum was unsuccessful, there were no tubercle bacilli present The patient was acutely ill for nine days and then recovered by crisis Roentgen-ray

on December 18 showed resolution of the lesion and a residual thickening of the interlobar pleura in association with a few hilar strands (figure 6)

In the studies of Sante⁶ and Hart⁷ on the postpneumonic lung it was found that pulmonary fibrosis and interlobar pleurisy were among the most frequent complications of lobar pneumonia. These residual effects were

FIG 4 (3-3-36) Case 2 Absorption of lesion, residual interlobar pleurisy and hilar fibrosis

noted in many of our cases. However, there were no follow-up roentgenologic examinations after hospitalization, and it is therefore impossible to state whether or not these shadows subsequently cleared up. In cases of apical pneumonia residual fibrotic lesions are of considerably greater significance than in lower lobe disease because it is more or less customary to in-

interpret all fibrotic infiltrations in the upper lobes as tuberculous without inquiring too carefully into the history of previous pulmonary infection. The clinical and radiologic course of illness in our patients unquestionably established the diagnosis as pneumonia rather than tuberculosis and yet the residual fibrotic infiltrations in no way differed from those seen after resolu-

FIG 5 (12-3-34) *Case 3* Pneumonic consolidation of left upper lobe, remainder of lungs negative

tion of exudative tuberculous lesions. The combination of interlobar pleurisy and pulmonary fibrosis occurred so often after the upper lobe pneumonias as to suggest these sequelae as the ordinary sequence of events. It is therefore obvious that the correct interpretation of these lesions is dependent on the history of the antecedent pulmonary infection.

FIG 6 (12-18-34) *Case 3* Absorption of lesion, residual interlobar pleurisy and pulmonary fibrosis extending from hilum (The apparent cardiac enlargement on this film is due to differences in radiographic technic from the previous one)

SUMMARY

1 A statistical study of 180 cases of lobar pneumonia at the City Hospital revealed the presence of upper lobe involvement in twenty-four (13.3 per cent)

2 Involvement of the right upper lobe predominated over that of the left in the ratio of 3:1

3 Examination of the sputum for tubercle bacilli was negative in all instances. Pneumococcus typing was negative for types I-XXXII in half of the cases, in the remainder there was no predominance of any type

4 The course of illness in most instances was characterized by marked toxicity

5 The mortality rate of all the cases was 42 per cent. The mortality rate of the cases with isolated upper lobe pneumonia was 21 per cent and of the cases with multiple lobe involvement 70 per cent.

6 The chief difficulties in the diagnosis are due to the frequent absence of physical signs of consolidation and to the similarity to the lesions of pulmonary tuberculosis. Lung abscess and meningitis may have to be considered also in the differential diagnosis.

HELIOOTHERAPY OF TUBERCULOSIS¹

By EDGAR MAYER, F A C P, *New York, N Y*

LIGHT therapy, both natural and artificial, is of definite value in the treatment of certain forms of tuberculosis. The clinically effective spectral regions are still to be defined, therapeutically, however, certain advantages are ascribed to sunlight as opposed to artificial sources of light, to one artificial source as against another and even to artificial sources as against the sun.

Empirical evidence still prevails, chiefly because the mode of action of light remains undefined. In the simplest photochemical effects, the physical processes are rarely understood and so the difficulties in biology and therapeutics are understandable. Not even upon the single cell have the effects of light been completely clarified.

Suggestive, however, are the laboratory experiments demonstrating effects upon the reticulo-endothelial system and upon capillary and cellular permeability with their resultant action upon immune processes and upon exchange of colloids and nutrition.

Empirically, however, sunlight represents one of the benefits of outdoor life making for physical and mental well-being. Experimentally in rickets, certain wave lengths of sunshine and artificial sources of light have been shown to be specific. In calcium-deficiency diseases such as rickets and infantile tetany and osteomalacia, ultraviolet energy has proved curative. However, to exaggerate the vital importance of light, either natural or artificial, and to make extravagant claims for it in therapy, employing it to the exclusion of hygienic and dietary regimes, is bound eventually to bring discouragement.

In tuberculosis the nature of the pathologic process must be defined before the indication for light therapy can be stated. Predominantly exudative disease indicates extreme caution, and in pulmonary tuberculosis presents a contraindication.

Benefits from light therapy are undoubtedly obtained by patients suffering from tuberculosis of the bones, articulations, peritoneum, intestine, lymph nodes and larynx when the entire body is exposed to carefully graded doses of natural sunlight or to radiation emitted by certain artificial sources of light rays. The beneficial results of such irradiation are due not only to ultraviolet rays. The visible and infra-red rays, as well as the conditions of the atmosphere, play a certain part in the therapeutic effect.

In superficial tuberculous ulcerations, healing, if it occurs, is due not to direct death of tubercle bacilli caused by ultraviolet energy, but to a local inflammatory or immune reaction of a nature still unexplained. Such ulcers may also heal during general body irradiation when the ulcer itself is un-

* Presented at the St. Louis meeting of the American College of Physicians, April 20, 1937.

exposed Direct irradiation of tuberculous ulcers of the skin, larynx, bronchi and bladder with various sources of ultraviolet has frequently promoted healing, failure may relate to improper dosage, technic or choice of source of radiant energy

In laryngeal tuberculosis, general body irradiation is often effective The acute forms, particularly those with edema, contraindicate local irradiation Vocal silence, bodily rest and electrocautery are much more effective

Oral and pharyngeal tuberculous ulcers, generally secondary, are most resistant to treatment

In tuberculosis of the skin, lupus vulgaris alone can be said to respond specifically to light Scrofuloderma and erythema induratum react favorably at times to general and local exposure, although not as constantly Papulo-necrotic tuberculids are resistant Lupus erythematosus does not respond to and may be aggravated by light

In tuberculosis of the bones and articulations, it is generally agreed that suitable, graded exposure to natural sunlight is most effective in promoting the healing accomplished by orthopedic and other measures Exposure to artificial sources of radiation is valuable as second choice Surgery, solar and artificial light therapy, braces, even in some cases the much maligned plaster-of-paris cast, all have their place in the treatment

It is not to be expected that light therapy will produce new cartilage in place of that which has been utterly destroyed, it does not make the process of fusion less necessary than it has been hitherto, but it can help this develop It is wrong to expect that its use will bring about regeneration of bone equal to that of a few vertebral bodies when they have been destroyed, but when this has occurred and a gibbous deformity exists, light therapy has aided orthopedic treatment in fusing these diseased surfaces especially when employed together with postural treatment

Surgical fusions are less commonly performed on children under 12 years of age If performed on adults or children, the disease must first show some evidence of retrogression, thus surgery is to help nature

Indications for surgical intervention may depend on economic and social conditions, the age of the patient, the joint involved, their number and the stage and extent of the disease, involvement of other organs such as the lungs and kidneys, and complicating abscesses or sinuses Surgical fusion is to be seriously considered in the presence of advanced joint destruction Restoration of function may occur in the synovial form of joint tuberculosis, even in the presence of large effusions, but complete functional return of motion in a joint is doubtful when the bony parts have been destroyed to a marked degree

Following operation, patients are still treated from one to two years, and during this period heliotherapy plays an important part Both mercury arc in quartz, and the carbon arc irradiations, employed as general and local exposures for prolonged periods of time, have proved helpful aids Small joints yield more quickly to conservative treatment than large ones The

knee joint is especially refractory, and particularly obstinate are old fistulas of the spinal column, pelvis or hip

Pulmonary tuberculosis per se is not an indication for light therapy. Uncomplicated exudative pulmonary tuberculosis is a contraindication to light therapy, with proliferative or fibrotic pulmonary tuberculosis, accompanied by elevation of temperature, sunlight or artificial lights, if employed at all, should be used cautiously. Intense sunlight should be avoided, and diffuse daylight or early morning and late afternoon sunlight should be used. Focal or constitutional reactions should be watched for. The indications here resemble those of tuberculin therapy.

In pulmonary tuberculosis, even when quiescent, harm has been done by sunlight exposures, especially with too intense and prolonged irradiations. Solar heat alone, especially in summer, can prove very harmful.

Stationary pleural tuberculosis has often been helped by light therapy. Tuberculous empyemas do not respond.

Genito-urinary tuberculosis deserves a trial of such treatment in combination with other measures. If unilateral renal tuberculosis is diagnosed at the very onset of symptoms and when such symptoms are slight, conservative treatment with light therapy has on rare occasions prevented the need of surgical intervention. As a rule, nephrectomy is indicated.

For unilateral progressive renal tuberculosis or bilateral disease in which the more involved kidney is removed, light therapy is to be advised as a desirable postoperative treatment. It may have a favorable action on the genital organs and the remaining kidney and effectively contribute to the healing of a tuberculous cystitis, whether alone or in association with medical treatment. Light therapy exercises a healing action on the stump of the ureter, which so often shows residual ulceration, resulting in a discharging sinus or a persistent cystitis. It has given excellent results, even with chronic gaping wounds, extensive and deep, and even when covered with ulcerations and tuberculous granulations.

Light is particularly indicated in those not infrequent cases of renal tuberculosis complicated by genital tuberculosis in which the seminal vesicles and prostate are involved, thus often obliging postponement of cystoscopy to avoid trauma of the prostate and the risks of general infection. Therefore, before surgical intervention it is advisable to treat the concomitant lesions with a methodical course of light therapy to make cystoscopy and nephrectomy procedures entailing less risk of dissemination.

In bilateral renal tuberculosis, light therapy is indicated. It may help render the disease quiescent, its occasional analgesic action on ulcerations of the bladder is particularly welcome.

Advanced bilateral renal and bladder tuberculosis has rarely responded to any form of therapy, especially when the patient is cachectic. Postoperative sinuses, especially following nephrectomy, have responded in a large number of cases to light therapy of all forms. Local exposure to ultraviolet rays of circumscribed tuberculous lesions of the urinary bladder has been

shown to yield favorable results, but the method requires special applying devices and, above all, skilful treatment of the bladder lesion

Ocular tuberculosis and aural tuberculosis respond infrequently to light. Corneal ulcers and phlyctenular conjunctivitis not infrequently heal under local exposures

Fistulas are often resistant to such treatment. Postoperative sinuses, in contrast, are most responsive

Intestinal tuberculosis of both the secondary ulcerative and hypertrophic forms especially indicates light therapy and often is rapidly responsive

Artificial light and solar therapy, as well as a rich vitamin diet, should be used in most cases, as they frequently relieve the symptoms and bring about recovery

Excellent results are obtained with the use of artificial sources of radiation, with general exposures either of the mercury arc in quartz, or flaming carbon arc sources. The results depend on factors such as the general status of the patient and the location, extent and nature of the disease in the intestine. Those with far advanced pulmonary and intestinal tuberculosis with little remaining resistance cannot be expected to respond, but intestinal tuberculosis today is healed in many patients, and autopsies have often confirmed this

The loss of symptoms is frequently surprising, abdominal pain and discomfort disappearing, diarrhea and fever subsiding quickly, and general improvement taking place. Roentgenologic studies show that the intestinal irritability as visualized by roentgen-ray defect clears up entirely in many instances

In peritoneal tuberculosis, light therapy always deserves a trial first. The serous exudative type generally responds to light irradiation, both in children and in adults. The dry proliferative form, usually adhesive, is more refractory. When there have been ulcerations and large caseous lymph nodes, as commonly seen in children, the results are most unsatisfactory. When the disease is of long standing, healing is more difficult than when irradiation is begun a short time after onset

The abdominal pain usually disappears rapidly under light therapy, especially in children. Large quantities of ascitic fluid may disappear in a few months

Tuberculous lymph nodes in the stage of hyperplasia generally heal under solar and artificial light therapy. Occasionally they caseate under light treatment and surgical excision may be indicated followed by postoperative light therapy. Caseous nodes respond although less constantly. Liquefied nodes require aspiration followed by light exposures. Sinuses from draining nodes indicate a course of light treatment. General and local irradiation are essential over periods of many months. Not infrequently roentgen-ray exposures may have to be combined. At times incision into a softening node is necessary

In tuberculosis, overdosage has produced harmful focal reactions. Light may set up a focal reaction similar to that of tuberculin.

The erythemic reaction is an accurate indicator of skin tolerance. A preliminary exposure of a small area to gauge the minimal perceptible erythema will generally avoid undue burns.

With any form of tuberculosis, light is to be used as an adjuvant only and should be combined with all other indicated forms of therapy. One of these, namely, roentgen therapy, has many restrictions and important contraindications, especially in pulmonary tuberculosis. Its healing effect in certain forms of extrapulmonary tuberculosis has been definitely established, but the limitations must be recognized, dosage carefully regulated, and treatments given only by experts in the field. The mainstays of treatment are still rest, proper dietary, and hygienic outdoor life.

THE SYNDROME OF EXTRARENAL AZOTEMIA^{*}

By HAROLD JEGHERS, M D, and HENRY J BAKST, M D,
Boston, Massachusetts

AZOTEMIA signifies an abnormal increase in the non-protein nitrogen (NPN) level of the blood. Normally the blood of a fasting person contains from 25 to 35 mg per cent of non-protein nitrogen, this includes urea, uric acid, ammonia, amino acid, creatine, creatinine and some nitrogenous substances known as undetermined nitrogen or rest nitrogen. Values for blood non-protein nitrogen over 40 mg per 100 c c are considered abnormal.

Theoretically an azotemia could be caused by an increase of any of these non-protein nitrogen constituents. The amounts of uric acid, ammonia, creatine and creatinine are so small that increases of even several hundred per cent would have but little effect on the total non-protein nitrogen. For practical purposes it can be considered that a noticeable increase in the blood non-protein nitrogen is usually due to alterations in the concentration of urea or undetermined nitrogen or both, and very rarely to changes in the amount of the amino acids.

The high non-protein nitrogen values and the clinical picture of uremia produced by bilateral diffuse and usually progressive kidney diseases, such as glomerular nephritis, nephrosclerosis, pyelonephritis, congenital cystic disease of the kidneys, mercuric chloride poisoning, renal tuberculosis, as well as by obstructive lesions in the lower genito-urinary tract due to tumor, stricture or enlarged prostate gland have been adequately described in medical literature.

On the other hand, but little attention has been directed to the fact that high blood non-protein nitrogen values may result from non-renal disease, or be due to functional or to minor pathologic disturbances of the kidneys which are often reversible under proper therapy. Prerenal or extrarenal azotemia are expressions often used to describe such types of azotemia which are not primarily due to renal disease. Unfortunately these terms imply a lack of participation of renal function in the production of the azotemia. Practically all conditions which are designated as prerenal or extrarenal azotemia are accompanied by functional renal changes and occasionally by minor degrees of renal damage. In many cases the term functional renal azotemia could more properly be applied, but because of long usage the term extrarenal azotemia should be retained. The concept of the syndrome should be expanded, however, to include diminished function of the kidney due to local functional, or even to minor pathologic changes. As will be pointed out later, these pathologic changes are often terminal events initiated

^{*} Received for publication August 24, 1937.

by purely extrarenal factors and cannot logically serve as the basis for the differentiation of a special group. They have been more or less neglected in texts dealing with kidney disease, and for that reason their importance has been overlooked.

Interest in this problem was stimulated by occasional examples of azotemia unrelated to organic kidney disease. A study of the literature in relation to these cases seems to indicate that the azotemia under these circumstances can be explained on the basis of one or more of six fundamental mechanisms. It is the purpose of this paper to present a review of these mechanisms, and to show by means of analyses of our own cases and of those collected from the literature that they will explain azotemia in all conditions not due primarily to organic kidney disease. An analysis of azotemia from this viewpoint allows a much more rational approach to therapy and clarifies an otherwise very confusing aspect of medicine.

BASIC MECHANISMS CAUSING EXTRARENAL AZOTEMIA

1 *Drop in Blood Pressure* It has been adequately established that the hydrostatic pressure in the glomerular capillaries furnishes the potential which induces glomerular filtration¹. The osmotic pressure of the colloids in the blood plasma may be set at about 30 mm of Hg in normal individuals². The glomerular filtration pressure is represented by the difference between the hydrostatic and the osmotic pressure. The hydrostatic pressure, which is directly dependent on the glomerular capillary pressure, is counteracted by the osmotic pressure of the plasma colloids. The effective glomerular filtration pressure is thus produced by the balance in favor of the hydrostatic pressure. Under normal circumstances the urine pressure in the intracapsular space and tubular lumina is too low to affect appreciably the filtration pressure³.

Lassen and Husfeldt⁴ studied the effect of changes in blood pressure on the renal function of normal individuals. A fall in blood pressure was produced by means of spinal anesthesia. It was noted that the urine volume diminished directly with the fall in blood pressure until a systolic level of approximately 70 mm of Hg was reached. As the blood pressure returned to normal, the volume of urine also rose. As a result of their studies, the authors felt that the systolic blood pressure of the peripheral circulation need fall but little below 70 mm of Hg before the production of urine would cease entirely. It is interesting to note that as the volume of urine decreased, the concentration (specific gravity) of the urine increased. It was concluded that with the lowered blood pressure due to spinal anesthesia, the glomerular function of the kidneys varied directly with changes in blood pressure whereas the tubular function remained unchanged as far as the resorption of water was concerned.

The above holds true for persons with normal blood pressure. It is well known that with advancing years the blood pressure rises and it is not

unusual for individuals past the age of 40 to have hypertension of many years duration. Wilkner⁵ raises the question whether or not this habituates the kidneys to depend on a higher filtration pressure, and argues that the threshold at which renal function diminishes in such individuals may be considerably higher than in those with normal blood pressure.

It seems clear, however, that a systemic blood pressure of at least 70 mm of Hg in normal individuals and perhaps higher in those with hypertension is necessary to maintain adequate renal function.

2 Hypochloremia and Hyponatremia In clinical medicine hypochloremia and hyponatremia are encountered in a wide variety of unrelated diseases. Persistent vomiting, gastrointestinal fistulae, diarrhea, excessive perspiration, rhinorrhea, evaporation from destroyed epithelial surfaces and polyuria are among the common causes of salt loss. More rarely, these blood electrolytes may be lost into body cavities (as in ascites) or into interstitial tissues (as in edema or shock). It is evident that in practically all of these cases, fluid loss accompanies the electrolyte loss. In addition, under experimental conditions and probably rarely in clinical practice dietary salt restriction may result in hypochloremia and hyponatremia.

In the past, attention for the most part has been directed to the chloride level resulting from these conditions. It should be emphasized at this point that sodium loss (in varying degrees) is usually associated with chloride loss. The influence of hypochloremia and hyponatremia on kidney function individually and collectively must be considered.

The frequent association of hypochloremia and azotemia has stimulated considerable experimentation and speculation. The many theories evolved and the contradictory experimental data derived have resulted in much confusion.

Blum and his co-workers⁶ believe that urea is retained in the body in order that the osmotic pressure of the body fluids may remain unchanged despite chloride loss. Peters,⁷ as well as Kerpel-Fronius and Butler,⁸ states that non-protein nitrogen may accumulate in the blood because the patients are dehydrated and are, therefore, unable to excrete the proper volume of urine. Peters⁷ and others believe in addition that increased destruction of body proteins may play a part when dehydration is severe.

Certain investigators, Brown et al.,⁹ believe that marked anatomical changes in the kidneys, especially the tubules, may be responsible for the nitrogen retention. Haden and Guffey¹⁰ and Mellinshoff¹¹ ascribe the azotemia to transient renal insufficiency of a purely functional type.

The experiments performed by Haden and Orr¹² in which animals were starved, their duodenum ligated and adequate fluid intake maintained were not conclusive, because Binet and Rathery¹³ repeated this work and showed that dehydration, as indicated by polycythemia, was present when this technique was used. The dogs in these experiments lived an average of four to nine days.

Since these results were not conclusive, Glass¹⁴ performed experiments

in which the chloride loss was definitely separated from dehydration. His dogs were given a carefully measured diet which was salt deficient but adequate in all other respects. The development of hypochloremia was also aided by gastric lavage before meals. By this technic Glass succeeded in producing hypochloremia without dehydration or starvation. The blood sodium level was not determined. The water content of the dog's blood plasma remained normal and the animals lived about 20 days in contrast to the much shorter period in Haden and Orr's experiments. Glass found that when the blood chloride loss reached 30 per cent, the urine and stools contained more nitrogen than could be accounted for by that contained in the food. The blood non-protein nitrogen became elevated slightly during the early part of the experiment and rose to very high levels shortly before death. The terminal stage resembled the clinical syndrome of uremia. Accompanying the terminal azotemia there was a diminution in the urinary excretion of nitrogen. This was interpreted as indicating an early rise of non-protein nitrogen due to an increased protein catabolism and followed by a terminal uremia associated with alteration of kidney function. The terminal rise of non-protein nitrogen and death could be prevented if sodium chloride was given to the animals before coma developed. In view of the fact that blood chlorides had to be reduced 30 per cent before these results followed, it was concluded that mild hypochloremia was less important clinically than pure dehydration.

Landis and his co-workers¹ have recently studied the relation between azotemia and hypochloremia and present an explanation supported by laboratory evidence. These investigators showed that when individuals were kept on a diet of known constant nitrogen intake as well as on adequate fluid intake, the average 24 hour urea clearance varied directly with sodium chloride restriction sufficient to produce hypochloremia. No attention was paid to the blood sodium level. The use of the 24 hour urea clearance technic explains their success as contrasted to the non-conclusive results obtained by other workers employing the standard two hour clearance. The level of the blood urea nitrogen rose with a restriction of the salt intake and the urea clearance diminished. In such individuals, treatment with sodium chloride without changing the nitrogen or fluid intake caused the 24 hour urea clearance to increase and the blood urea nitrogen to drop to normal.

In these cases the authors argued that neither dehydration nor oliguria per se explained the changes in renal function since the fluid intake averaged 4500 c c and the urinary output 3000 c c per day. These experiments were interpreted as indicating that the chloride level of the blood must be considered a factor in renal function entirely distinct from the fluid intake. There is also considerable clinical evidence to support this experimental work indicating that the administration of sodium chloride in selected cases is an aid to renal function^{6, 16}.

McCance¹⁷ produced salt deficiency in four persons with normal kidneys. They were given a plentiful intake of water but caused to perspire profusely

and to take a sodium chloride free diet. Azotemia developed in each case. Renal function was studied in one of these persons. The urea clearance was found to be only 60 per cent of normal. Clausen,¹⁸ on the other hand, could not confirm the findings of Landis or McCance. He was unable to demonstrate any correlation between the blood chloride level and the urea clearance test, or between chloride therapy or restriction and the urea clearance test.

Groak¹⁹ in dogs and Clausen¹⁸ with humans produced azotemia by injection or oral ingestion of large amounts of urea. In no case did the blood chloride level change. They were of the opinion that the chloride level as such did not influence nitrogen elimination.

Kerpel-Fronius²⁰ opened up an entirely new approach to the problem. By means of experiments on rabbits it was shown for the first time that with azotemia due to salt restriction, the important ion was the sodium and not the chloride. Hypochloremia without hyponatremia was produced in one set of animals, in the other the blood sodium was reduced. The animals with hypochloremia, but normal sodium levels, showed no dehydration or azotemia. The group with low blood sodium showed dehydration and azotemia despite an adequate fluid intake.

It remained for Gomori and Podhradzky²¹ to point out the true significance of the above experiments as applied to azotemia in humans. They believe Kerpel-Fronius' experiments are unimpeachable proof that hypochloremia plays no direct part in the development of azotemia, while sodium restriction by leading to dehydration can cause azotemia.

Basic studies by Gamble²² show that where sodium is lost the body loses the corresponding quantity of water, this loss being from the plasma and interstitial fluids. Gamble's explanation is that the body tries to compensate for the lowered osmosis by a corresponding decrease in water content. In spite of the loss of sodium, the plasma concentration of this ion does not decrease appreciably but the quantity of circulating plasma does decrease. This causes a dehydration similar to direct water reduction. If the blood sodium is low, an increased water intake is of no avail since the newly added fluid does not remain for long in the plasma. Thus, Gomori and Podhradzky²¹ feel that salt deficiency by producing hyponatremia can cause dehydration even though the fluid intake remains adequate. They attribute the resulting azotemia to the dehydration.

From this recent work it is evident that the cause of the confusion with regard to this subject centers in the fact that many investigators have paid attention to only the chloride portion of the problem. It is also evident that both hypochloremia and hyponatremia influence renal function but by different mechanisms. It is well known, as shown by Gamble,²³ that the loss of electrolyte from the body is always associated with fluid loss, and conversely that fluid loss is associated with loss of electrolytes. What has been overlooked is the fact that the electrolytes are not always lost in the same proportions in various body fluids. For example, the patient who vomits loses fluid, much chloride (as HCl) and but little sodium. This results in a

marked hyponatremia but with relatively normal blood sodium level ²³ On the other hand, the loss of pancreatic fluid through a fistula causes a marked hyponatremia with considerably less change in the blood chloride level The proportional loss of sodium and chloride varies with different body secretions and excretions

Chloride loss can probably affect renal function only because of the concomitant loss of fluid which is entailed In this respect, hyponatremia must be considered among the causative mechanisms of extrarenal azotemia Hyponatremia, on the other hand, seems specifically to produce a diminished blood plasma volume irrespective of the fluid intake or loss The azotemia which follows sodium chloride restriction is probably intimately linked with the sodium factor

Aside from the influence on water balance and the level of the nitrogenous products one must not overlook that loss of electrolytes results in a shift of the acid-base balance of the body If sodium is lost in excess of chlorides (i.e. pancreatic juice) acidosis results On the other hand, chloride loss in excess of sodium (i.e. gastric juice) results in alkalosis In this respect, varying degrees of acidosis or alkalosis may accompany the syndrome of extrarenal azotemia

3 *Dehydration* That ordinary dehydration may affect renal function has been well established on the basis of scientific investigations and routine clinical experience Lashmet and Newburgh ²⁴ have shown that under normal conditions the kidneys excrete 35 to 40 grams of solids per day Each gram of this waste material requires about 15 c.c. of fluid to be dissolved Therefore even with kidneys working to maximal concentration, at least 500 to 600 c.c. of urine must be excreted per 24 hours to avoid the retention of nitrogenous waste products in the blood If the kidneys are unable to concentrate to the maximal specific gravity of 1.032, more fluid is required to eliminate the total solids This has been carefully worked out by them and is shown in the accompanying table ²⁵

| Maximum Concentrating Ability | | Minimum Amount of Water Required to Excrete 35 grams of Waste Material |
|-------------------------------|-------------|---|
| Specific Gravity | | Cubic Centimeters |
| Normal | 1.032-1.029 | 473 |
| Diseased | 1.028-1.025 | 595 |
| | 1.024-1.020 | 605 |
| | 1.019-1.015 | 850 |
| | 1.014-1.010 | 1,439 |

In individuals with normal kidneys, the volume of urine is more or less directly related to the fluid intake This has been adequately and conclusively shown by Coller and Maddock ²⁶ who performed experiments planned to demonstrate the effects of pure dehydration on renal function In their experiments all other factors known to affect renal function remained con-

stant throughout. The subjects were healthy adults who were permitted light muscular activity. The environment was such that sweating did not result. A diet of low fluid content, just sufficient to cover the caloric requirements, was given. The mineral content of the diet remained constant throughout with an adequate salt intake so that no disturbance of the mineral balance of the body resulted. These subjects were then dehydrated by merely restricting the fluid intake.

The important changes were found in the blood and urine. The non-protein nitrogen of the blood rose in each case from normal figures of 30 to 32 mg per cent to 40 to 45 mg per cent after two to four days of dehydration. The urines before dehydration showed an average specific gravity of 1.015 with volumes ranging from 1200 to 1500 c c. With dehydration the specific gravities in each case increased to values of from 1.031 to 1.041, while the daily urinary output dropped to 440 to 480 c c. The urine on the last day of dehydration exhibited traces of albumin, many casts and some red cells. This was an interesting demonstration of the lack of specificity of the presence of albumin, casts and red cells in the urine as indicative of organic renal disease.

Following treatment with fluid alone these abnormal findings in both the blood and urine reverted to normal within one or two days. These experiments seem to indicate that pure dehydration entirely aside from salt restriction or loss may have a definite deleterious effect on renal function. In addition to producing oliguria with its concomitant retention of nitrogen in the blood, dehydration may also cause azotemia by other mechanisms. Meyler²⁷ in particular has stressed the point that dehydration increases protein catabolism. This has been borne out by other investigators²⁸. It should not be overlooked that dehydration by reducing the circulating blood volume may produce shock with its accompanying lowering of the blood pressure. These factors are probably effective only in the severer degrees of dehydration.

Except under strict experimental conditions and rare clinical circumstances, dehydration per se does not occur except in conjunction with loss of body electrolytes. Dehydration without salt loss would, therefore, be expected particularly in instances of restricted fluid intake with normal consumption of food. Possibly to be considered with dehydration is shock. Here blood is shunted from the active vascular tree into stagnant body depots such as the liver, spleen, splanchnic area and sub-papillary capillary plexuses. Aside from the drop in blood pressure, renal function is impaired under such circumstances by the lack of available fluid in the active circulation. The blood passing through the kidneys is dehydrated even though no fluid is lost from the body as a whole.²⁹

With dehydration there occurs hemoconcentration which entails an increase in viscosity of the blood.³⁰ This probably hinders the circulation through the kidney. Medes³¹ has shown that decreased blood flow through the kidneys leads to a diminution of the glomerular filtrate. Dehydration

also increases the concentration of total blood protein³² The influence of this fact on renal function will be discussed later

In summary then, dehydration affects renal function by limiting the available fluid for excretory purposes, increasing protein catabolism, diminishing the flow of blood through the kidneys, lowering of the blood pressure, and probably by increasing the colloid osmotic pressure of the blood

4 *Liver Damage* Although many of the metabolic functions of the liver were known earlier, it was not until the work of Mann and his co-workers³³ that certain of these functions were definitely established Of particular interest in relation to the subject under discussion is the experimental proof presented establishing the liver as the site of catabolism of amino acids with the consequent production of urea Bollman, Mann and Magath³⁴ in studies on hepatectomized dogs, found that in no case did deaminization occur after the liver had been removed This was demonstrated by the recovery of amino acid in the blood, urine and tissues of these animals in amounts approximately equal to the anticipated formation of urea If amino acids were injected into these animals the entire amount of amino acid nitrogen was recovered unchanged in the blood, thus little or no urea is formed in the absence of liver function In these experimental animals, although the total non-protein nitrogen increased, this increase was associated with an absolute reduction of urea nitrogen and a marked rise in the amino acid nitrogen of the blood

Clinically this has a definite bearing in cases of advanced liver destruction Prior to the experimental work of Mann and his co-workers, Stadie and Van Slyke³⁵ reported a case of acute yellow atrophy which demonstrated these findings Even more striking, however, is the case of extreme liver destruction reported by Rabinowitch³⁶ in which the amino acid nitrogen rose to 216 mg per cent (as contrasted with normal value of from 5 to 8 mg per cent) No urea could be demonstrated in this instance From a similar point of view, Stander³⁷ in reporting a chemical study of chloroform poisoning, found an increase in the total blood non-protein nitrogen with which was associated an increase in the amino acid nitrogen More recently the studies of Wakeman and Morrell³⁸ on experimental yellow fever in monkeys demonstrated that in this disease, which is characterized by liver cell damage, the blood urea nitrogen, although increased in most instances, did not increase in proportion to the total non-protein nitrogen In some cases it showed an actual decrease The difference in every case was made up chiefly by a rise in the amino acid nitrogen and undetermined nitrogen

In the past few years there have been many case reports of azotemia subsequent to varying degrees of liver damage in which the rise in total non-protein nitrogen was due to a rise in the urea nitrogen rather than the amino acid nitrogen Few of these cases, however, have received adequate study from the point of view of various other factors such as hypochloremia, hyponatremia, drop in blood pressure, dehydration and renal function

This recognized deaminizing function of the liver demonstrates the im-

portance of both amino acid and blood urea nitrogen determination in persons with liver disease. Obviously in the absence of such determinations no true understanding of elevated non-protein nitrogen in liver disease can be obtained.

5 *Protein Catabolism* Under ordinary circumstances the level of the non-protein nitrogen of the blood is dependent on (1) the adequacy of renal function in eliminating nitrogen in the urine, (2) on the amount of water available to perform this function and (3) on the rate at which protein is broken down in the body³⁹. With proper function and available fluid present, an increased rate of protein catabolism is reflected up to a certain point by an increase in urinary excretion of nitrogen. It seems reasonable to assume then that protein catabolism may occur at so rapid a rate that even normal kidneys are ineffectual in removing all of the nitrogen products produced, or too rapidly for normal kidneys to be adjusted immediately to this increased demand. In either case an increase in the level of the blood non-protein nitrogen will result.

The importance of protein catabolism in controlling the level of the non-protein nitrogen of the blood has been emphasized by Peters and Van Slyke⁴⁰. They have pointed out that unless the rate of nitrogen catabolism and the urine volume are known, the blood non-protein nitrogen cannot be utilized as a criterion of renal function. Conversely, it would seem that in the presence of normal renal function and urine volume, an increase in the blood non-protein nitrogen can be associated with increased protein catabolism.

In controlled starvation experiments Lennox et al⁴¹ demonstrated fluctuations in the blood non-protein nitrogen presumably due to uneven protein catabolism. A previous investigation in animals had been made. Morgulis and Edwards⁴² reported an increase of the non-protein nitrogen and blood urea nitrogen at an early stage of fasting which remained at a more or less fixed level until the extreme stage was reached when a much greater increase occurred. The amino acid nitrogen and creatinine remained more or less constant but the undetermined nitrogen rose somewhat. The investigations of both of the above groups indicate that on re-feeding, for a time less nitrogen is excreted than ingested. It would seem likely, therefore, that the non-protein nitrogen which leaves the blood in these instances is not excreted but used in building body protein.

Morgulis and Edwards⁴² and Mackay and Mackay²⁸ have shown that when water as well as food is restricted, the rise in the non-protein nitrogen is exaggerated. The latter investigators reported the additional increase of non-protein nitrogen in dehydration experiments further prolonged by intravenous injections of sucrose. Peters and Van Slyke⁴³ point to this rise of non-protein nitrogen as the result of augmentation of protein metabolism and consider it as an example of toxic destruction of protein. Meyler²⁷ has presented evidence to indicate that dehydration may be an important factor in increasing protein catabolism. It is also considered by some²⁷ that

acidosis may play a similar rôle Glass,¹⁴ in the experiments previously mentioned, was able to show that chloride (? salt) loss leads definitely to some degree of protein destruction

In a series of experiments on the effects of protein intoxications and injury of body protein Cooke and Whipple⁴⁴ and their collaborators⁴⁵ point out the occurrence of high non-protein nitrogen with sterile abscess formation, septic inflammations such as pleurisy, pneumonia and peritonitis in experimental animals, and in man with septicemia, peritonitis and pneumonia. In these works the azotemia was accepted as an indication of increased protein catabolism in the presence of anatomically normal kidneys

Recently Lurje⁴⁶ in continuing the investigations on protein metabolism in instances of severe surgical trauma in cases with intact innervation of the liver has demonstrated an increase in the amino acid nitrogen of the blood which appears to be due to a reflex provoking endogenic breaking down of proteins

Cases reported by Rackemann, Longcope and Peters⁴⁷ of nitrogen retention occurring in the course of acute allergic states are very interesting in view of the interpretation that these are due to some degree of tissue injury. Also, Hashimoto⁴⁸ has shown that with histamine intoxication similar changes in the blood chemistry take place. Although protein metabolism is believed to be partly responsible for this change, it must not be forgotten that at autopsy Hashimoto⁴⁸ found marked degenerative changes of the tubular epithelium

In extensive studies of nitrogen metabolism as affected by iodides Grabfield and Prentiss^{49, 50} determined that iodides caused an increased nitrogen excretion probably resulting from increased nitrogen catabolism. In the case of potassium iodide, however, the deleterious effects of potassium on kidney function must be remembered

To recapitulate, there seems to be evidence to indicate that the factors of starvation, dehydration, acidosis, salt loss, infections, fever, trauma, allergy, and certain drug intoxications may all be associated with increased protein catabolism. There is some doubt, however, as to whether these factors operating independently can produce a significant degree of azotemia. It is perhaps better to consider them as contributory factors, since under actual clinical circumstances, they are usually interrelated with other mechanisms capable of producing azotemia

6 Local Renal Disturbance That progressive organic kidney disease may alter renal function is so well known that it requires no further comment. On the other hand that minor changes in renal tissue may cause alterations in function which are often reversible is not so well appreciated. These may occur in a wide variety of unrelated systemic diseases, and are characterized by diversified change in the kidney parenchyma and resultant alterations in renal function. Only too often are these minor changes noted at autopsy with no attention paid to them in explaining physiological dis-

turbances Likewise, it is often overlooked that disturbances in the kidney of a functional nature can result in diminution of excretion of urine

The factors which influence the output of the urine will be briefly reviewed in order that the concept under consideration may be more clearly understood Cubitt,³ in a recent review on renal physiology summarizes them as follows (1) The urine pressure, (2) Changes in the secretion-reabsorption activity of the tubule cells, (3) The blood pressure in the glomerular capillaries, (4) The area of the capillary bed from which filtration is taking place, (5) The osmotic pressure of the colloids in the plasma of the blood contained in the glomerular capillaries, (6) Nervous control and (7) Hormonal control

Whether changes in the secretion—reabsorption activity of the tubule cells can account for changes in renal function is still problematical It is possible that the activity of the tubule cells may be changed by alteration in blood supply, pressure of urine within the tubules, and microscopic changes within the tubule cells For a similar reason the control of the area of the capillary bed from which filtration can take place must be disregarded It can not be measured readily in the living, nor can it be seen in anatomical material It is evident that the control of this area must depend on systemic blood pressure, nervous influences presence or absence of chemical substances or hormones present in the blood, and on the state of relaxation and contraction of the afferent and efferent arterioles controlling the blood supply to the glomeruli Since the kidney normally needs but a small fraction of its total glomeruli for normal renal activity, it seems unlikely that anything except a diffuse change would result in loss of renal function severe enough to cause nitrogen retention Because the afferent and efferent arterioles are under nervous and chemical control it is conceivable that a widespread loss of effective filtering area could result through some humoral stimulation or nervous reflex

The principal function of the renal nervous control is regulation of the vasomotor functions with vaso-constrictor action predominating Any stimulation of the splanchnic trunk (either directly or perhaps indirectly from a distance by reflex action) lessens the amount of urine secreted Conversely, depression or section of the splanchnics increases the amount of urine⁵¹ There is no good evidence that nerves carry secretory fibers⁵¹ The nature of reflex anuria is obscure and will be discussed in detail later

The effect of the systemic blood pressure on urinary function has already been mentioned It was pointed out that the effective filtration pressure depends on the difference between the hydrostatic pressure of the blood due to the general arterial blood pressure, and the counter pressure due to the osmotic tension of the serum proteins This holds true as long as the urine pressure on the tubular side of the glomerular membrane is not increased Normally the intracapsular urinary pressure is nil and can be disregarded Any rise of the urine pressure in the intracapsular and tubular spaces, however, interferes with the effective filtration pressure Such in-

creases in urine pressure can result from partial or complete obstruction of the kidney tubules

Under normal circumstances the colloid osmotic pressure of the blood rarely exceeds 25 to 30 mm of Hg². This pressure depends chiefly upon the blood proteins. It is well known that in severe states of dehydration hyperproteinemia results³². Gorom and Podhradszky²¹ measured the colloid osmotic pressure in animals before and after dehydration. The average normal for cats before dehydration was 33 mm of Hg. Even though the albumin-globulin ratio reversed with dehydration, the osmotic pressure of the blood proteins increased, reaching in some cases over 60 mm of Hg. They considered the hyperproteinemia due to dehydration an important factor operating within the kidney in the extrarenal azotemic syndrome. This effect is obtained by counteracting the glomerular filtration pressure.

Changes in the renal tubules are not specific and may occur in the course of a wide variety of clinical conditions. Not only are the clinical pictures with which they are associated variable, but often the changes themselves vary from microscopic degeneration to evidence of gross necrosis and, on occasion, are entirely absent. In addition, obstruction can occur from precipitation of material present in the glomerular filtrate, thus occluding the tubular lumina⁵². It would appear that these changes are not necessarily progressive in nature, and, as a rule, disappear as the patient recovers from the systemic condition with which they are associated. They are noted at autopsy only when a patient dies during the course of disease prone to produce tubular damage. At this time changes varying from cloudy swelling to actual necrosis of tubular epithelium with inspissation of granular debris in the lumina of the tubules may be noted.

Experimentally it has been shown that advanced as these changes may be, if given the opportunity, regeneration and presumably return of normal function will take place⁵³. These tubular changes (even though anatomical) must be considered as appertaining to the mechanisms of this syndrome, since they are often produced by the prolonged presence of factors of purely extrarenal origin. The widespread presence of such changes can cause the kidney volume to be increased and the capsule of the kidney to be distended. At autopsy, such kidneys are increased in weight and are grossly edematous and swollen, with bulging of the cortex when the capsule is cut.

These changes in the anatomical structures of the tubular cells invariably result either in an increase in the size of the cells or in the extrusion of cellular debris into the tubular lumina. The end result in either case is a diminution of tubular patency which in turn increases the urine pressure within the tubular and intracapsular space. If the increase in urine pressure is sufficient it may counteract effective filtration through the glomerular capsule and lead to retention of nitrogenous waste products in the blood³.

The cause of tubular changes is not clear. One possible explanation is illustrated by the interesting series of animal experiments performed by

Hashimoto⁴⁸ He showed that after the intravenous injection of 1 to 3 mg of histamine dichloride evidence of intoxication could be expected. This toxicity was associated with a rise of the blood non-protein nitrogen, fall of blood pressure, and markedly diminished urinary flow. The post-mortem findings were definite and characteristic, consisting of diffuse degenerative changes in the tubular epithelium with no changes in the glomeruli. One cannot fail to recognize the resemblance between this picture of histamine shock as described by Hashimoto, and that of extrarenal azotemia as depicted in this paper. In view of the possibility that histamine, or a histamine-like substance, may be liberated in many shock-like states, it seems more than justifiable to include histamine as one of the possible factors in the production of extrarenal azotemia.

Aside from these anatomical changes in the tubular epithelium another mechanism may lead to an increase in urine pressure with a consequent diminution in renal function. It should not be overlooked that the systemic venous pressure when increased may lead to congestion and edema of the kidney. The capsule of the kidney prevents renal distention beyond a certain volume. Therefore, as venous pressure rises, the intrarenal pressure is also increased and is transmitted equally in all directions. At a certain point this will necessarily result in compression of the tubules and thereby raise the urine pressure within the intracapsular space. This in turn diminishes the effective filtration pressure and may lead to oliguria and azotemia. In addition to its effect in increasing the urine pressure, venous congestion influences urinary function by diminishing the blood flow through the kidney and by producing an anoxemia.⁵⁴

One cannot overlook the possibility that renal function may be partially influenced by hormonal control. Of the various endocrine glands in the human body, there is evidence that specific hormones from the pituitary gland and the adrenals exert such an influence.

The diuresis inhibiting action of posterior pituitary lobe extract in man has been recognized for many years. Starling and Verney produced this effect on an isolated kidney and it has further been shown that the effect is not altered by denervation of the kidney. This indicates that the anti-diuretic effect of posterior lobe extract is primarily on the kidneys. Although the exact site of action in the kidneys is still undecided upon, the bulk of the evidence seems to indicate that the antidiuretic action of this hormone is due to increased reabsorption of water without much change in the rate of glomerular filtration.⁵⁵ The indiscriminate use of pituitrin, especially in postoperative cases where the fluid balance is readily disturbed, may well be a significant factor in producing azotemia.

Loeb et al.⁵⁶ have demonstrated that adrenal cortical substance influences sodium excretion. This has been well substantiated by others. In considering the azotemia found in Addison's disease, Loeb and his co-workers⁵⁶ were unable to explain it by purely extrarenal factors. From the evidence on hand, they postulated "that the adrenal cortical substance acts on the

kidney to control the excretion not only of sodium but also of urea. In adrenal insufficiency, the rate of salt excretion is increased while urea elimination is retarded." This hypothesis is attractive in view of the adenal damage commonly found in severe infections and certain toxic conditions (i.e. burns) in which azotemia is not uncommon.⁵⁷ It is evident that a disturbance in adrenal physiology may at times play a rôle in the initiation of extrarenal azotemia.

Discussion It should be kept in mind that these six mechanisms, although presented separately, are interlinked and often interdependent. This method of presentation serves merely to clarify an otherwise extremely complex exposition. The interrelationship of these mechanisms is well exemplified by a hypothetical situation. In a patient who has a severe diarrhea, there is an entailed loss of fluid, sodium and chloride with resulting dehydration and diminution of the circulating blood volume. There is then an associated fall of blood pressure. Starvation, dehydration, fever and hypochloremia would increase protein catabolism. If the patient is severely toxic, renal tubular damage may supervene. This combination of circumstances brings on the extrarenal azotemic syndrome. One can imagine many situations in which the combinations of mechanisms would be much simpler and others where they would be more complex.

The concept of extrarenal azotemia cannot be rationally expounded without considering factors operating locally in the kidney. Renal tubular damage or tubular occlusion may be found terminally in many cases with azotemia primarily due to extrarenal factors. It is not, however, an invariable finding. For this reason such cases can more rationally be placed in the extrarenal syndrome than segregated in some unsatisfactory subgroup of organic renal disease.

The very term "extrarenal" is a poor one, but serves as a useful designation to separate this type of azotemia from that due to the well recognized organic renal diseases. All the extrarenal factors (no matter how far distant from the kidney may be their source) produce, either directly or indirectly, some effect which operates directly in the kidney.

PATHOGENESIS OF EXTRARENAL AZOTEMIA IN VARIOUS CLINICAL CONDITIONS

Azotemia occurs frequently in clinical conditions other than those associated with organic kidney disease. This type of azotemia is extrarenal in origin. While it is more commonly seen in certain clinical states, it may be present in any disease in which the above mentioned mechanisms are operative. An attempt is made here to indicate the pathogenesis of extrarenal azotemia by analyzing the responsible mechanisms in a series of chosen clinical conditions which are illustrated in part with our own case histories. A similar approach is possible under any circumstance in which azotemia occurs in the absence of organic kidney disease.

1 Coronary Thrombosis

Case 1 A 63 years old man was admitted to the Evans Memorial Hospital with a two day history of precordial distress, faintness, vomiting, restlessness and dizziness. Significant physical findings included cyanosis, slight dyspnea, a few râles at the bases of the lungs, distant heart sounds of tic-tac quality, and a pulse rate of 140. Blood pressure was 90 mm of Hg systolic and 70 mm of Hg diastolic. Temperature was 100° F.

The first urine specimen had a sp gr of 1.025, a slight trace of albumin, no sugar, and a few leukocytes and casts per high power field in the sediment. Subsequent specimens of urine were of even higher specific gravity. The leukocyte count was 20,000 with 85 per cent polymorphonuclear neutrophils. The electrocardiographic findings were typical of an acute coronary occlusion. The patient rapidly grew worse and died two days after entry. The blood pressure and pulse were unobtainable for 24 hours before death.

The pertinent laboratory data are summarized in table 1.

TABLE I

| Date | B P | Blood N P N mg % | Blood Urea N | CO ₂ Combining Power | Whole Blood Chlorides | Sp Gr of Urine |
|--------|-------|------------------------|--------------------|---------------------------------------|-----------------------------|-------------------|
| 1/6/37 | 90/70 | 45 | 20 | 57 | 433 | 1.025 |
| 1/7/37 | ? | 71 | 38 | 49 | 370 | 1.030 |

The autopsy revealed the presence of considerable sclerosis of the coronary vessels with massive infarction of the left ventricle. Grossly the kidneys were normal. Microscopically the glomeruli were normal, but the tubular cells were swollen, often acidophilic, with some of the lumina containing granular debris.

The occurrence of azotemia in coronary thrombosis is not often mentioned but Steinberg⁵⁸ found the non-protein nitrogen of the blood to be over 40 mg per cent in 20 of 31 cases. An analysis of the mechanism of the disease readily explains this frequency of azotemia. A drop in blood pressure, even to shock levels, is common. The effect of this on renal function has already been discussed. The other major factor contributing to azotemia is the diminution in the volume of circulating blood. This may be due in part to vomiting, sweating or to fluid restrictions. The chief cause, however, as shown by Fishberg et al⁵⁹ is the redistribution of the blood, whereby a smaller fraction of the total volume of blood in the body remains in active circulation, and a larger fraction stagnates in dilated capillaries and perhaps within the blood depots. In other words, the features of the shock syndrome are prominent. This, by limiting the fluid available for renal excretion, further influences the retention of nitrogenous waste products.

The urinary findings have been strikingly presented by Steinberg⁵⁸. Most urines showed high concentrations, specific gravities of 1.020 or higher, with the presence of albumin, casts and occasionally red blood cells. In a few instances urinary suppression was complete. Oligurias with 24 hour volumes of 500 c c or less were common.

Starvation, destruction of body protein, toxic damage to renal tubular cells and venous congestion due to heart failure may at times play lesser rôles in producing the azotemia

As shown by Steinberg,⁵⁸ and by analysis of the above factors, it is obvious that a blood non-protein nitrogen which remains elevated or continues to rise is of ill omen and offers a poor prognosis. Serial blood non-protein nitrogen studies and urine analyses should be included along with the electrocardiogram, white blood count and sedimentation rate in evaluating cases of coronary thrombosis.

Case 1 is a classical example of azotemia due to coronary thrombosis. Postmortem examination showed that the kidneys were essentially normal for this person's age, except for the recent tubular changes. Vomiting, drop in blood pressure and the shock syndrome were the responsible factors. The urine with its high specific gravity of 1.025 to 1.030 and the presence of albumin, cells and casts was characteristic. There was in addition a mild hypochloremia. Tubular damage was probably minimal.

2 Alkalosis

Case 2 A 31 year old man was admitted to the Boston City Hospital with a history of a duodenal ulcer of several years' duration. A dietary regime and alkaline powders had afforded relief until about eight months previously when symptoms recurred. The patient then resorted to daily self-induced vomiting. He became nervous and irritable, and developed vertigo, nocturia and shooting pains and aches in both legs.

Physical examination showed epigastric tenderness, tenderness of the leg muscles and active reflexes. His blood pressure was 120 systolic and 90 diastolic.

The history, examination, laboratory data and course are typical of alkalosis.

The significant laboratory data are given in table 2.

TABLE II

| | N P N mg % | Plasma Chlorides mg % | CO ₂ Comb Power Vol % | P S P % | Urine Sp Gr | B P | |
|------|---------------|-----------------------------|--|------------|----------------|----------|-----------|
| | | | | | | Systolic | Diastolic |
| 4/13 | 130 | 430 | 82 | 6 | 1.010 | 120 | 90 |
| 4/14 | 120 | 485 | 65 | | 1.014 | 120 | 80 |
| 4/15 | | 500 | | | | | |
| 4/20 | | | 60 | | | | |
| 4/22 | 98 | 508 | 45 | 10 | | | |
| 4/29 | 82 | 520 | 40 | | 1.011 | 120 | 80 |
| 5/30 | 63 | 585 | 42 | 20 | 1.012 | | |
| 6/24 | 50 | 588 | 42 | 28 | 1.010 | 120 | 80 |

The patient was given four liters of fluid daily with 30 grams of sodium chloride. Alkalies were omitted. The vomiting ceased after one week, and the nocturia disappeared after the first month.

The syndrome of alkalosis is characterized chemically by azotemia, hypochloremia, and increased carbon dioxide combining power. It may oc-

casionaly occur solely from excessive loss of hydrochloric acid (vomiting of gastric juice) The blood sodium level may be normal Ingestion of alkali by persons with organic renal disease readily causes alkalosis In addition ingested alkaline salts may cause alkalosis if the fluid and chloride balance of the body are disturbed by vomiting, hematemesis, or excessive sweating This phase of the subject is discussed at length elsewhere by Jeghers and Lerner⁶⁰ In addition, it has been shown that severe alkalosis can cause damage to the tubules of the kidney, thus further diminishing renal function⁹ When tubular damage occurs, loss of ability to concentrate the urine may follow The process seems to be reversible if treatment is prompt

It is uncertain whether the ingestion of alkalis can cause renal impairment in a person with normal kidneys unless some auxiliary mechanism be present A case reported by Steele⁶¹ suggests that it can A man, aged 52, had ingested alkalis for years There was no evidence of renal disease prior to this therapy Renal failure developed without clinical symptoms of alkalosis The blood urea nitrogen rose, phenolsulphonaphthalein excretion and urea clearance were diminished, urinary concentration was fixed at a sp gr of 1.010 and albumin casts and red cells were present in the urine Withdrawal of alkalis caused a prompt drop in blood urea nitrogen It was not until three years later that urinary function was entirely normal

Case 2 is an interesting example of alkalosis An admission to the hospital four years before had shown normal renal function The ingestion of alkaline powders, in the presence of diminished chloride and fluid due to vomiting initiated the syndrome Renal tubular damage resulted Even when the blood chemical findings had returned to normal, the phenolsulphonaphthalein excretion was still low and the urine specific gravity fixed at a low level This patient was seen one year after discharge, at this time he had regained normal renal function, including ability to concentrate

3 *Pyloric Obstruction*

Case 3 A 61 year old man was admitted to the Boston City Hospital, complaining of anorexia, pain in the left flank, small nodules in the skin and loss of weight

Scattered pea-sized, non-tender nodules were made out in the subcutaneous tissue of the face, neck and back A walnut-sized nodule was palpable in the left supraclavicular fossa The blood pressure was 175 systolic and 100 diastolic A vague sense of resistance was made out just above the umbilicus

The kidneys showed an ability to concentrate to a maximum of 1.033 On occasions a slight trace of albumin was noted, otherwise the urines were negative The non-protein nitrogen was 35 mg per cent on admission, but two days later the patient developed intractable vomiting and the non-protein nitrogen rose to 125 mg per cent The plasma chlorides fell from 570 to 426 mg per cent Death occurred one week after admission The blood pressure remained well sustained

The autopsy revealed extensive carcinomatosis with metastases to the vertebrae, pelvis and skin The primary lesion was an obstructive pyloric carcinoma The

combined weight of the kidneys was 270 grams and they were grossly and microscopically within normal limits

That azotemia may complicate pyloric obstruction has been well shown, both experimentally and clinically⁹ The above case is a good example of azotemia due to this cause The mechanism is easy to understand Vomiting causes loss of fluid and of chloride The effect of this on renal function has already been discussed In this particular case, the renal tubules were normal at autopsy Occasionally if the syndrome is prolonged, tubular damage may result with concomitant loss of power to concentrate the urine With the tubules normal, as was the case here, the urine is highly concentrated and scanty

4 *Peritonitis*

Case 4 A 59 year old woman was admitted with a known history of a peptic ulcer of ten years' duration Three days before she had developed sudden epigastric pain, abdominal distention and vomiting The vomitus became blood-streaked, probably from retching

On entry the patient was semi-stuporous, the skin was dry, râles were heard at both bases, and the blood pressure was 60 systolic and 10 diastolic The abdomen was distended and tender, most markedly so in the right lower quadrant Definite tenderness was noted on rectal examination The temperature was 97° F, the pulse 120, and the respirations 30

After admission the temperature rose to 102°, and she lapsed into coma The urinary output was only 40 c c in 24 hours despite the fact that fluids were forced The patient died four days after admission

The specific gravity of the urine was 1.019, a very slight trace of albumin was noted and a moderate number of leukocytes and rare granular casts was seen in the sediment The non-protein nitrogen on admission was 55 mg per cent and rose to 100 mg before death

The autopsy confirmed the clinical impression of peritonitis resulting from a ruptured duodenal ulcer The combined weight of the kidneys was 240 grams Microscopic examination revealed the presence of a minimal degree of nephrosclerosis and considerable swelling of the tubular epithelium which in some places was desquamated

In peritonitis we have many mechanisms operating to produce an azotemia Dehydration is caused by vomiting and shift of available circulating blood volume Salt loss will usually accompany this fluid loss Blood pressure is often low Fever, infection, and starvation increase protein catabolism In addition, it is not unknown for the tubular epithelium of the kidney to show changes varying from swelling to actual necrosis with plugging of the tubular lumina This adds a local renal factor to those of extra-renal origin Case 4 shows how all these factors can be operative in a single patient

5 *Liver-Kidney Syndrome* There has been considerable discussion in the recent literature concerning the so-called liver-kidney syndrome^{62, 63} Chief interest has been centered in the attempt to find the noxious agent which is supposedly elaborated by a damaged liver and which secondarily

affects renal function⁶⁴ It is obvious that the azotemia in many of the cases of this syndrome which have been reported, can be explained on the basis of the mechanisms discussed in this paper A recent paper by Lichtman and Solval⁶⁵ emphasizes this point of view The following two cases illustrate this point

Case 5 A 35 year old woman was admitted to the Boston City Hospital, with a history of eructations and of vomiting once or twice weekly for six months Jaundice and weakness had been noted for two weeks, and the patient had become delirious 24 hours before her admission

Physical examination showed a markedly icteric skin with scattered petechial hemorrhages The tongue was dry The liver edge was not felt but the spleen was palpable 1 cm below the costal margin Respirations were 12, pulse 104 and the temperature 102° F Blood pressure was 70 mm Hg systolic and 50 mm diastolic

The specific gravity of the urine was 1.032, there was a slight trace of albumin The sediment was loaded with granular and hyaline casts The patient could not be roused from her coma and died 12 hours after admission The blood non-protein nitrogen was 250 mg per cent

The autopsy revealed petechial hemorrhages in all the serous surfaces The liver was very small, weighed 680 grams, and showed the characteristics of acute yellow atrophy The combined weight of the kidneys was 260 grams Bile staining, and degeneration of the tubular epithelium, and hemorrhages about the tubules of the cortex and medulla were noted microscopically

It is unfortunate that complete chemical studies were not available in this case, but in view of the very high non-protein nitrogen and the extremely small liver, certain deductions are warranted The azotemia here may well have been mostly amino-acid nitrogen retention due to massive liver destruction This case closely resembled the one reported by Rabino witch³⁸ which showed a liver weighing 650 grams, dehydration and fall in blood pressure

Case 6 A 67 year old man was admitted to the hospital because of the development of nausea and vomiting one and one-half weeks after an injection of neoarsphenamine It had also been noted that the skin had become yellow and the urine dark in color

On physical examination a moderate degree of jaundice was observed The abdomen was tympanitic and distended and the liver edge was made out 8 cm below the costal margin The temperature was 98° F, the pulse 100 and the respirations 18

The maximum specific gravity of the urine was 1.027 A very slight trace of albumin was present and an occasional granular cast was noted in the sediment

The patient gradually became worse, and the liver edge seemed to recede about 1 cm daily At the end of a week he developed generalized edema, sank into a quiet coma and died The pertinent laboratory findings are given in table 3

The autopsy showed an extensive hepatitis presumably due to arsphenamine The combined weight of the kidneys was 360 gm Microscopically they showed bile staining and a moderate degree of degenerative change in the tubular epithelium

In this case the azotemia was due to retention of urea nitrogen The amino acids remained normal Dehydration was minimal The single chloride determination gave a high normal value The low level reached

TABLE III

| Date | N P N mg % | Blood Urea N mg % | Amino Acid mg % | Uric Acid mg % | Plas- ma- Chlo- rides mg % | T P gm % | Alb Glob | | B P mm of Hg | |
|-------|---------------|----------------------------|-----------------------|----------------------|--|-------------|----------|-----|--------------|-----------|
| | | | | | | | gm | % | Systolic | Diastolic |
| 11/9 | 30 | | | | | | | | 115 | 70 |
| 11/18 | 74 | 34 | | 2 5 | 671 | 6 8 | 2 9 | 3 9 | 70 | 50 |
| 11/20 | 60 | 44 9 | 7 2 | | | 7 0 | | | 40 | 20 |

by the blood pressure was striking Autopsy showed evidence of mild damage to the tubular epithelium of the kidneys

6 *Yellow Fever* In a series of careful studies on the chemistry and metabolism in experimental yellow fever Wakeman and Morrell³⁸ pointed out that, although the blood urea nitrogen increased in most instances, it did not increase in proportion to the rise in the total non-protein nitrogen In some instances the urea fraction was actually decreased, a proportionate increase occurring in the amino acid nitrogen and also in the "rest nitrogen" The terminal increase in the non-protein nitrogen was further accentuated in most cases as a result of late shock In such instances the blood pressure dropped markedly and oliguria or anuria developed A part of the terminal increase in the azotemia may also be due to the high rate of protein destruction characteristic of the disease The ability of the kidneys to produce urine of normal concentration seems to be almost unimpaired throughout the disease

7 *Gastrointestinal Hemorrhage*

Case 7 A 50 year old man was perfectly well until 10 hours before admission to the hospital when he had sudden nausea and began vomiting blood About a quart of blood was vomited by the time he was admitted to the hospital A history of chronic alcoholism was obtained

On admission the patient was obviously in shock, the pulse was weak and thready and the respirations were 26 per minute The blood pressure was 95 systolic and 55 diastolic The remainder of the physical examination was not remarkable

The patient was given morphine and intravenous fluids He continued to vomit blood On the second day he was given a transfusion of 500 c c and saline clyses, and seemed somewhat improved On the fourth day, however, he began vomiting again, the temperature rose to 100° F and he died

The pertinent laboratory findings are given in table 4 The urines showed a specific gravity of 1 014 and were otherwise negative

TABLE IV

| Date | Hgb per cent | R B C in millions | W B C | N P N mg per cent |
|---------|-----------------|----------------------|--------|----------------------|
| 7/29/34 | 70 | 4 2 | | |
| 7/30/34 | 69 | 3 2 | 21,800 | 81 |
| 8/2/34 | 50 | 2 4 | | 218 |

The effects of blood loss on the level of the blood non-protein nitrogen were clearly indicated by Taylor and Lewis⁶⁶ and later by Buell⁶⁷ More recently, particularly in Denmark,⁶⁸ this problem has received considerable careful attention It seems clear that at times massive gastrointestinal hemorrhage can cause a marked azotemia

Here, as in other conditions, several factors come into play which may affect renal function Large hemorrhages are associated with varying degrees of dehydration, salt loss, lowering of blood pressure and hemoconcentration It has in addition been postulated that the reabsorption of digested blood from the gastrointestinal tract could directly influence protein metabolism⁶⁹

Often in hemorrhage, the problem is not one of blood loss particularly, for the quantity of blood lost may be considerably less important than the resultant degree of shock with fluid shunted from the active vascular circuit into stagnant depots Not to be overlooked is the starvation and fluid restriction that such persons are subjected to as part of the treatment of the bleeding

8 *Postoperative*

Case 8 One week before admission this 42 year old woman noted pain in both lower quadrants which increased in severity Anorexia and nausea developed, with some burning on urination

On physical examination tenderness and spasm of the lower abdomen were noted A doughy mass in the posterior cul-de-sac was palpable during the course of a painful rectal examination The temperature was 97° F, pulse 100 and respirations 25 The leukocyte count was 25,000 with 93 per cent polymorphonuclear neutrophils

The specific gravity of the urine was 1020, a trace of albumin was present, a moderate number of leukocytes and a few coarse granular casts were seen in the sediment The non-protein nitrogen was 57 mg per cent

A laparotomy, performed two days after admission, disclosed a bilateral purulent salpingitis with peritonitis The fallopian tubes were removed and the abdomen drained Two days after operation the temperature rose to 101°, the pulse remained at 100, but the respirations rose to 30 On the eighth day the patient developed a generalized convulsion and thereafter frequent muscular twitchings were noted The non-protein nitrogen rose to 240 mg per cent, pain and swelling of the right parotid appeared, and the patient lapsed into coma and died

The autopsy revealed the presence of peritonitis and bilateral bronchopneumonia The combined weight of the kidneys was 395 gm The capillaries were engorged, the tubular epithelium swollen and, in places, desquamated Many of the tubules were distended with amorphous albuminous material and some of the lumina contained hyaline casts

Postoperative rises of blood non-protein nitrogen are extremely common if one performs routine blood chemistries This aspect of the subject has been recently discussed by Derow⁷⁰ The significance of insufficient fluid intake, lowered blood pressure, pituitrin medication, vomiting and increased body protein destruction was emphasized Not mentioned but of interest, is the possible presence of renal tubular damage which would add a local anatomic renal factor to the above mentioned impairments of physio-

logical functions Case 8 illustrates many of these mechanisms in a single patient Of note also in this case were the muscular twitchings which are classically seen in uremia

It is obvious from the data on hand that in all postoperative patients daily examination of the urine, with special reference to the 24 hour volume and specific gravity, should be performed Periodic blood chemical examinations would be of additional aid From these, one could detect an azotemia long before it became manifest clinically and could plan the therapeutic procedures more efficiently Pituitrin should be used with due caution

9 Congestive Cardiac Failure

Case 9 A 32 year old white man, admitted to the Boston City Hospital, had noticed progressive dyspnea, edema of ankles, cyanosis and a feeling of distress in his abdomen for 16 months The past history was not satisfactory Physical examination revealed a well nourished man, markedly cyanosed The peripheral veins were distended The lungs were free of rales The heart was enlarged, the pulmonic second sound was accentuated and a rough systolic murmur and thrill were noted over the apex The rhythm was regular and the pulse was 88 The blood pressure was 118 mm Hg systolic and 75 mm diastolic The liver was enlarged 6 cm below the costal edge and was tender There was soft pitting edema of legs, buttocks and sacrum

The urine contained an infrequent slight trace of albumin and 1 030 represented the maximum specific gravity The hemoglobin was 93 per cent (Sahli), erythrocytes numbered 5 5 million and the leukocytes 8,300

During the patient's hospital stay, the peripheral edema and cyanosis increased, the liver enlarged and eventually showed a systolic pulsation as did the distended neck veins The patient's condition grew steadily worse, and four days before death jaundice appeared which gradually increased in intensity The blood non-protein nitrogen on admission was 31 mg per cent but rose to 100 mg per cent two days before the onset of jaundice The blood pressure level was maintained until the end After a month, the patient sank into a deep coma and on the day before his death uremic snow was noted on the cheeks and sides of the neck The urinary output was diminished but the specific gravity remained at 1 030

The autopsy revealed rheumatic heart disease with mitral stenosis, tricuspid regurgitation and right ventricular hypertrophy Multiple pulmonary infarcts were present Chronic passive congestion of the liver, spleen and lungs was noted The combined weight of the kidneys was 285 gm The width of the cortex was 7 mm Microscopically the kidneys were normal except for congestion

Numerous studies of renal function during heart failure have been made^{71, 72} Foster⁷³ demonstrated that an increased non-protein nitrogen of the blood may result purely from circulatory disturbances In a study of eight cases of congestive heart failure he found an average non-protein nitrogen of 61 mg per cent with extremes of 40 and 90 mg per cent Four of these cases were examined after death and showed no evidence of renal disease

Sustained high venous pressure can cause congestion of the kidneys Even normal kidneys can accommodate for this congestion only to the limit of the distensibility of their capsules Congestion beyond this point pre-

sumably results in the compression of available space within the kidney, particularly the tubular lumina, eventually interfering with kidney function

The findings in Case 9 appear to justify a simple mechanical explanation of this sort. There was no change in blood pressure, no dehydration and no salt loss. This case, in addition, showed certain classic clinical features of uremia. The uremic frost was marked. The terminal stupor progressing to coma resembled that seen in organic kidney disease.

10 Intravenous and Transfusion Reactions

Case 10 A 46 year old man was admitted to Boston City Hospital, for treatment of an indolent ulcer of the left leg believed to be due to Buerger's disease. Previous admissions had revealed no findings of significance except those referable to partial occlusion of the arteries of both legs. The blood pressure had always remained about 130 mm Hg systolic and 80 mm diastolic. The renal function was normal. Physical examination on this admission revealed no new signs. The patient was treated by means of 200 c.c. of 5 per cent saline given three times weekly. He did well and after several weeks the ulcer began to heal.

A month after admission, following by one hour an injection of 5 per cent saline intravenously, the patient had a severe chill and began to vomit. The next morning jaundice was noticed. The pulse increased to 120 while the temperature rose to 103° F. The jaundice increased, the face and extremities became puffy, the conjunctivae chemotic, and hemorrhagic manifestations appeared. Significant changes in the laboratory data are tabulated in table 5. Unfortunately the presence or

TABLE V

| | Blood Pressure | | N P N | Sp Gr Urines | Urinary Volume | Icterus Index |
|---|----------------|-----------|----------|-----------------|---|------------------|
| | Systolic | Diastolic | | | | |
| Before reaction | 130 | 80 | 25 mg % | 1.020 | Normal | 4 |
| After reaction (only extremes tabulated) | 140 | 80 | 155 mg % | 1.028 | Progressive diminution to complete anuria | 100 |

absence of hemoglobinuria was not ascertained. The liver was slightly palpable. Repeated blood cultures showed no growth. The patient continued on a progressively downhill course, developed anuria, lapsed into coma and died five days after the onset of the reaction. The postmortem examination revealed a normal sized liver with scattered areas of necrosis, atherosclerosis of the peripheral arteries and terminal bronchopneumonia. Blood cultures were negative. The combined weight of the kidneys was 540 gm. The cortex was 1.2 cm wide. Microscopically there was no evidence of vascular or glomerular involvement. The convoluted and collecting tubules contained granular material. The tubular epithelium was somewhat flattened.

This bizarre clinical picture resembles closely that reported in other instances as following certain transfusions^{74, 75}. Hench⁷⁶ reported a quite similar reaction following the intravenous injection of typhoid vaccine. This naturally raises the question as to whether some common mechanism underlies these seemingly isolated types of reactions.

An analysis of the above case shows that salt loss, dehydration and hypotension were not operative here. Liver damage was not sufficient to be a factor. Excessive protein catabolism alone could scarcely be responsible for a rise of blood non-protein nitrogen to 155 mg per cent. The kidneys showed evidence of tubular damage and much debris blocking the tubular lumina. It thus seems that the local renal factor was most important here.

This appears to agree with the results secured by DeGowin et al.⁵² in explaining a similar syndrome due to blood transfusion reactions. These workers showed that in acid urine, the excretion of hemoglobin caused obstruction of the tubular lumina with masses of pigment derived from hemoglobin. Unfortunately, in our case, no search for hemoglobinuria was made. The hemolysis of blood caused by the injection of any deleterious substance would allow us to explain these reactions on a mechanism similar to the one proposed by DeGowin et al.⁵² Further study is obviously needed.

11 *Weil's Disease*

*Case 11** A 38 year old man was admitted to the Boston City Hospital severely prostrated and jaundiced. For one week, weakness, muscle pains, prostration, chills, vomiting and progressive jaundice had been noted. Physical examination revealed severe icterus, moist râles in the chest, hemorrhagic herpes of the lips, mucous membrane bleeding, a distended abdomen and tender thigh muscles. Blood pressure was 120 mm Hg systolic and 50 mm diastolic.

The urine was highly concentrated, and contained albumin and many granular casts. There was a leukocytosis of 28,700. The non-protein nitrogen of the blood was 200 mg per cent, the sugar 55 mg, the cholesterol 90 mg and the total protein 4.4 gm per 100 cc. The blood phosphorus was 13.6 mg and the calcium 10 mg per cent. The patient lapsed into coma and died 16 hours after admission.

The postmortem findings were typical of Weil's disease. The combined weight of the kidneys was 530 gm. The cortex was 8 mm wide. Microscopically, interstitial infiltration of a multicellular type was noted, for the most part in the medulla. Some of the tubules were dilated and their epithelium showed evidence of regeneration. In certain tubules granular debris was present. In about a fourth of the convoluted tubules there was swelling of the epithelial cells with narrowing of the lumina. Spirochetes were found in the convoluted tubules.

Azotemia is constantly present in the second stage of severe cases of Weil's disease.⁷⁷ In mild cases it may be absent. It is well known that tubular damage and blocking of the renal tubules by granular debris are commonly present in this disease. In view of the close similarity between Weil's disease and yellow fever, one must not overlook the possibility of liver damage contributing to the azotemia. This has been shown to be so for yellow fever.³⁸ Dehydration is in addition common. The tubular changes must be considered reversible, since the patients who recover regain entirely normal renal function.

12 *Addison's Disease*

Case 12 A 12 year old girl was admitted to the Evans Memorial Hospital in a moribund state. For six months she had had progressive fatigue, weakness, anorexia,

* This case was previously reported in detail.⁷⁷

vomiting, weight loss, cramp-like pains in the abdomen and legs, and bronzing of the skin. Physical examination revealed prostration, emaciation, bronzed and pigmented skin and mucous membranes. The pulse was 108, the blood pressure was 74 mm Hg systolic and 44 mm diastolic.

The blood sugar was 68 mg per cent and the non-protein nitrogen 120 mg.

The postmortem findings were consistent with the clinical diagnosis of Addison's disease, both adrenals showing marked atrophy. There was no evidence of tuberculosis. The combined weight of the kidneys was 225 grams, they showed no gross changes. Microscopically there was no evidence of vascular or of glomerular disease. There were slight engorgement and edema with some lymphatic infiltration. About one-third of the tubules showed swelling of the epithelium, with eosinophilic cells and pyknotic nuclei. Some of the lumina were filled with granular debris.

Marshal and Davis⁷⁸ first pointed out the occurrence of a rise in the non-protein nitrogen of the blood following adrenalectomy. This was also found fairly consistently by Rowntree⁷⁹. Later Loeb and his co-workers^{80, 86} demonstrated the urinary loss of sodium associated with adrenal insufficiency. This loss of sodium, chiefly as chloride, was then confirmed by other workers. It was suggested that the adrenals probably exert a regulating influence on body sodium.⁸⁶

Other factors besides this loss of sodium influence the elimination of non-protein nitrogen from the blood in Addison's disease. The loss of sodium chloride is associated with varying degrees of dehydration. Also the typical asthenia of this disease is associated with a progressive lowering of the blood pressure. As already discussed in this paper, Loeb et al.⁸⁶ have suggested that the lack of the adrenal cortical substance acts specifically to cause urea retention in the blood stream.

In view of this patient's youth and lack of history of renal disease it was felt that this case was of particular interest here. This viewpoint was justified by the minimal degree of renal damage seen at autopsy. All changes are confined to the tubules, only about a third of which were involved and those only to a degree which would generally be termed moderate.

13 *Pneumonia*

Case 13 A 45 year old negro was admitted to the Boston City Hospital, complaining of cough and dyspnea. He had been well until five days before when he had a chill, and subsequently began to cough and raise small amounts of whitish sputum which was sometimes blood-streaked. There was no chest pain. He had been perspiring profusely during the past four days. There was no history of previous renal disease.

On physical examination of the chest signs of consolidation were found in the upper portion of the right lung and in the base of the left lung. The blood pressure was 110 mm Hg systolic and 60 mm diastolic. The temperature was 103° F, pulse 140 and respirations 50.

The urine had a specific gravity of 1.014, contained albumin but no casts or pus cells. The hemoglobin was 86 per cent, the leukocyte count 10,800. A type V pneumococcus was obtained from the sputum and blood. The non-protein nitrogen was 70 mg per cent.

The patient's condition grew rapidly worse and he died two days after admission.

The autopsy revealed the presence of lobar pneumonia of the right upper and left lower lobes with extension to all remaining lobes. The combined weight of the kidneys was 360 grams. The width of the cortex was 0.5 cm. Microscopic studies showed minor degrees of tubular damage. The glomeruli appeared normal. Some of the tubular lumina contained granular debris.

In view of the discordant results of earlier investigations, Farr and Abernathy⁸¹ carefully studied the renal function in 28 cases of pneumonia. The urea clearance test indicated an actual increase in this type of renal function in the pre-critical stage of the disease particularly in the younger age group (i.e. up to an age of 40). They concluded that in the pre-critical phase of pneumonia renal function may be elevated, unchanged, or slightly impaired. In general they noted that the level of renal activity was inversely proportionate to the age of the patient.

Of particular interest are two cases in their series which exhibited high blood urea nitrogen values on admission, with low urea clearance, both of which returned to normal during the next few days. It was felt that these patients were probably dehydrated and that extrarenal factors played a dominant rôle in the production of these changes.

The occurrence of hypochloremia during the course of lobar pneumonia has been recognized for some years⁸². Several workers have found the sodium to be diminished as well⁸⁵. Low total base values have likewise been reported⁸⁵. More recently, Atchley⁸³ has brought forth the conception that a shock-like state exists in pneumonia, with accompanying dehydration, and hemoconcentration⁸⁴.

To go one step further, it has been noted that, with various infectious diseases including pneumonia, it is not unusual to find hemorrhagic necrosis of the adrenals post mortem⁸⁷.

In summary, then, increased protein catabolism, dehydration, electrolyte disturbance, lowered blood pressure and toxic damage to the adrenals and kidneys are significant factors in producing azotemia in pneumonia.

Case 13 is illustrative of azotemia in pneumonia. It was not well enough studied to permit critical evaluation of the factors responsible. At autopsy the evidence of renal tubular damage was striking.

14 *Allergy*. Rackemann, Longcope and Peters⁴⁷ in 1916 confirmed the fact that in serum disease there was often a marked but transient retention of chlorides and of water, associated frequently with albuminuria, cylindruria, and sometimes with impaired phenolsulphonephthalein excretion. The kidneys in these cases showed an impaired ability to eliminate chlorides and loss of power to concentrate urine. The following year Longcope and Rackemann⁸⁶ reported two interesting cases of azotemia associated with attacks of urticaria. In each case with the onset of the acute allergic state, albumin and casts appeared in the urine, the phenolsulphonephthalein excretion diminished and the blood non-protein nitrogen rose (in one instance the blood urea nitrogen reached a level of 290 mg per cent). Plasma chloride values were low. Even with so high a degree of nitrogen reten-

tion as that mentioned, the patients recovered rapidly and completely. The cases were not studied from the viewpoint of this paper and therefore the exact mechanism responsible is not clear. There seems little doubt that allergic states can produce an azotemia of extrarenal origin.

15 *Diabetes Mellitus* Many clinicians and investigators are aware of the frequent association of diabetic coma and azotemia⁸⁷. This is often erroneously attributed to kidney disease.

Peters et al.,⁸⁸ in a study of the total acid-base equilibrium in diabetics, called attention to (1) the loss of fluid because of glycosuria, polyuria, base excretion and vomiting, (2) loss of base bound to ketones which are thus excreted in the urine, and (3) the availability of base released from chloride for ketone neutralization. It was pointed out that the result is a state of dehydration and salt depletion as well as acidosis. Atchley and Benedict⁸⁹ arrived at similar conclusions. The dehydration causes a decrease in blood volume with consequent decrease in blood pressure and increase in the percentage of blood proteins.

McCance and Lawrence⁸⁷ reviewed the proposed mechanisms supposedly explaining the production of extrarenal azotemia in diabetic coma and concluded that no proposed mechanisms including dehydration, failing circulation, low blood pressure, excessive protein catabolism, action of insulin, ketosis and salt depletion could be invariably and wholly responsible for the extreme and consistent degrees of nitrogen retention which occurred in some of their cases. These authors believe that another mechanism must be present. They point to the similar occurrence of nitrogen retention in Addison's disease and conclude that the causes may be similar, that is a deficiency in fixed base which may be brought about not merely by acidosis and diuresis but possibly by a partial failure of the suprarenal cortex.

16 *Shock* Moon⁹⁰ has been able to show that the advanced stages of shock are invariably associated with an increased blood non-protein nitrogen. Drop in blood pressure and loss of circulating blood volume seem to be the chief factors concerned. Moon⁹⁰ lists a large group of diseases in which severe shock (and therefore azotemia) occurs. Blood is lost by being shunted into stagnant depots. Also, changes in capillary permeability cause loss of fluid and electrolytes into interstitial tissues.

17 *Acute Pancreatitis* DeTakats and Mackenzie⁹¹ recorded a case of pancreatitis with azotemia. They expressed the view that it would commonly be found if examinations of the blood chemistry were routinely performed in this disease. The same mechanisms used to explain azotemia in shock probably apply here.

18 *Diantheal Diseases* As one would expect, fluid and salt loss are the chief initiating factors⁹². Not to be overlooked are fever, starvation, and infection, all of these can increase protein catabolism. With severe dehydration the blood pressure falls. Toxic damage to kidney tubules may occur.

19 *Heat Cramps* Talbott⁹³ has demonstrated that in heat cramps the

blood sodium and chloride are diminished. Hemoconcentration and azotemia are constant features. The disease is initiated by excessive loss of sodium chloride in the sweat. Here is an interesting example of dehydration due to sodium loss. In most cases these persons continued to drink water which is, however, of no avail until the sodium chloride loss is replaced.

20 Drug Intoxication A few drugs seem to affect nitrogen metabolism. Of these, the iodides are probably the most outstanding. Grabfield and his co-workers⁴⁹ showed that the continued use of potassium and sodium iodides may cause an increase in the output of nitrogen in the urine. Potassium iodide particularly may cause an increase in the blood non-protein nitrogen, amounting sometimes to 30 per cent of normal values and occasionally reaching abnormal figures. These results were attributed chiefly to an increased rate of protein catabolism. The possible deleterious effect of potassium on kidney function must not be forgotten.

Of the chemicals and poisons which may affect kidney function indirectly, phosphorus and chloroform³⁷ are the most common. If the kidneys are not directly involved, azotemia may result because of liver cell destruction, and consequent loss of the ability of the liver to deaminate amino acids. An increased rate of protein catabolism may be present. More often than not, actual renal insufficiency supervenes, and the blood urea nitrogen increases in relation to the increasing urea threshold in the kidney.

21 Burns The relation of superficial burns to azotemia is important. In 1923 Underhill and his co-workers⁹⁴ demonstrated that many of the constitutional effects of extensive burns were due to the presence of marked hemoconcentration. This was borne out by the fact that improvement followed in most instances when the normal blood volume was restored.

At about the same time Robertson and Boyd⁹⁵ stressed the factors of primary shock occurring in those cases which terminated fatally within the first 24 hours, and toxic shock which resulted in a later death. The latter very likely is what is now recognized as the syndrome of hemoconcentration.⁸⁴

Later Davidson⁹⁶ in studying the sodium chloride metabolism of patients suffering from burns found a significant lowering of the blood chlorides. In general, the disturbance of chloride metabolism was proportionate to the amount of devitalized tissue. Davidson also believed that an increased rate of protein catabolism accompanied lesions of this sort.

Recent investigators have focused their attention sharply on sodium metabolism and the adrenal glands.⁵⁷ As evidence accumulates it seems more and more probable that adrenal hormonal regulation with control of sodium metabolism and restriction of urea excretion may be a basic factor in conditions of this type. The presence of pathological changes in the adrenals noted at postmortem examinations of patients who have died as a result of severe burns would appear to give added weight to this point of view.⁵⁷

In summary then the lowered blood pressure, increased protein catabolism, hyponatemia and hypochloremia, dehydration and toxic damage to the adrenals are chiefly responsible for the azotemia found in burns

CLINICAL PICTURE OF EXTRARENAL UREMIA

The clinical picture of the classical type of uremia due to organic kidney disease has been well reviewed by Fishberg⁹⁷ and more recently by Harrison and Morton⁹⁸ Fishberg⁹⁷ defines uremia as "a complex autointoxication, the variegated clinical picture being the summation of the effects of retention of various urinary constituents, largely, it would seem, end-products of protein catabolism" He further remarks "no group of symptoms is to be considered as uremic in nature unless it occurs in the presence of abnormally high non-protein nitrogen in the blood"

The mechanisms described in this paper can undoubtedly cause the retention of other substances besides the nitrogenous waste products This would fulfill the requirements of the above definitions Harrison and Morton⁹⁸ state that the syndrome of prerenal azotemia resembles true uremia in both its chemical and clinical aspects

True uremia will always be found a concomitant part of the clinical picture of organic renal failure Since few renal diseases are fulminating, the symptoms are often present for weeks or months

Extrarenal uremia, on the other hand, must of necessity be superimposed on the clinical features of many widely varied and entirely unrelated diseases Further, the diseases which cause this type of uremia are usually acute and fulminating, their duration being one of days For this reason the clinical manifestations of chronic uremia (i.e. yellowish pallor of the skin, pericarditis, uremic colitis with diarrhea, severe anemia, extreme dryness of the skin, uremic eruptions and emaciation) are but rarely seen The chief features of extrarenal uremia seem to be fatigue and drowsiness, progressing into stupor and coma within a period of a day or longer Case 9 in our series showed the classical deposit of uremic crystals on the skin Case 8 presented muscular twitchings What should be particularly emphasized is that we lack a careful chemical analysis of cases falling into this group and that such a study is needed in order to define more clearly the clinical picture of extrarenal uremia Whether the non-excretory functions of the kidneys are affected in this syndrome to a degree sufficient to be clinically detectable is at present not known Snapper⁹⁹ believes them important in explaining uremia

ANURIA

One hears only too frequently such expressions as "the patient's kidneys have closed down, the patient has developed reflex anuria, etc" Even more unfortunate is the fact that many physicians treat all oliguric and anuric patients in a routine fashion without attempting to evaluate properly and specifically treat the factors responsible for the diminished or absent kidney

function. It is evident that the problem of anuria is closely linked with the problem of azotemia. Essentially, anuria may be looked upon as an exaggerated degree of oliguria. Therefore, a discussion of the mechanisms involved in the production of anuria will clarify both subjects.

The most satisfactory working classification of the anurias is that which divides them into one of the following categories: (1) Prerenal, (2) Renal and (3) Postrenal.¹⁰⁰

Prerenal In prerenal anuria the causative factors lie outside of the kidneys and genito-urinary tract. It is immediately evident that this type of anuria represents but a severe degree of several of the mechanisms previously discussed, that a drop in blood pressure sufficient to nullify the intraglomerular pressure will produce anuria, and that severe degrees of dehydration and sodium chloride deficiency may also produce anuria.

The existence of reflex anurias has been disputed. That splanchnic stimulation can diminish urinary function is well established. The usual reflex anuria means complete cessation of function in one kidney following some catastrophe to the other.¹⁰⁰ It has been suggested also that stimuli to the renal splanchnics may arise from nerve insults outside of the renal system causing an inhibition of function of all renal tissue. Such a mechanism if it exists must be included with the prerenal group of anurias. It would explain anuria following such widely varied events as immersion in cold water, hysteria, and operations on organs distant to the genito-urinary tract. Of interest is Cubitt's statement³ that most case reports in which reflex anuria has been postulated do not contain blood pressure measurements nor facts relating to other mechanisms controlling renal function.

Renal Anuria Renal anuria refers to factors operating primarily within the kidney. In addition to diffuse inflammatory lesions, chemical damage, neoplastic invasion, mechanical destruction, removal, congenital defects and degenerative changes, one must also include edema of the kidneys due to venous congestion or tubular occlusion due to nephrotic changes. These latter two have already been discussed under local conditions causing azotemia. When of severe degree they can readily produce anuria.

Postrenal Postrenal anuria refers to the type due to mechanical factors causing obstruction to the outflow of urine. These are either bilateral or unilateral and in the latter instance may be associated with reflex anuria or subnormal renal function of the opposite kidney.¹⁰¹ The majority of the cases falling in this category are due to ureteral calculi or strictures or to urethral obstruction. Where the possibility of this type of anuria exists the patient should be studied intensively by urological methods.¹⁰¹

Discussion The foregoing classification allows a more rational approach to the problem of anuria. It is evident that an understanding of the mechanisms involved clarifies the study of any particular case. By discarding obscure and complicated classification dependent primarily on the relationship between anuria and a wide and varied number of systemic con-

ditions, one's attention is necessarily focused on the few fundamental mechanisms involved in the production of anuria

The treatment of anuria will necessarily depend on the primary disturbance by which it is produced. If obstructive lesions of the genitourinary tract and intrinsic renal disease are ruled out, the remaining mechanisms which produce anuria are the same as the mechanisms discussed under the production of prerenal and functional azotemia, and should be treated in a similar fashion

METHODS OF DIFFERENTIATING AZOTEMIAS

Since the mechanisms producing azotemia are numerous, it is evident that a somewhat elaborate diagnostic study of cases of unexplained azotemia will be necessary. The first consideration in explaining any azotemia should be the investigation of whether true organic renal disease, or the mechanisms discussed in this paper are responsible

Renal lesions which produce true uremia, as a rule, cause changes in the urine distinct from those seen in functional azotemia. Fishberg comments on this fact⁹⁷. In true uremia the specific gravity is usually fixed at a low level, often 1.010, and only rarely as high as 1.015. In sharp contrast is the specific gravity of the highly concentrated urine of functional azotemia which may range as high as 1.040. Exceptions to this are some of the cases with severe tubular damage as a complication to the extrarenal factors. Here the specific gravity may be lower. These changes, however, develop far more rapidly than in the usual organic renal diseases.

The volume of urine is not so important since it may be diminished in both types. It is evident that the finding of albumin, casts and cells in sediment is often of little differential value. The general clinical picture will probably be the most important aid in determining whether or not organic renal disease is present.

If it is believed that azotemia is of the type discussed in this paper an effort should be made to determine which of the basic mechanisms is present. This may entail detailed laboratory study of the case, but since functional azotemia is frequently reversible, a knowledge of the causative mechanisms will often point to therapy which may prove life saving.

From this point of view the minimum information needed would include: The systemic arterial blood pressure, 24 hour fluid intake and urinary output, measurement of fluid lost by extrarenal channels, urinary specific gravity, presence or absence of ketonuria, blood sodium, blood chloride, carbon dioxide combining power, total blood protein, erythrocyte count, hemoglobin, hematocrit value, and blood non-protein and urea nitrogen. If the patient has liver disease a nitrogen partition of the blood should be performed including the amino-acid nitrogen. In the case of congestive heart failure or obstruction of the inferior vena cava, the venous pressure obtained in the femoral vein would be of value. The factor of protein cata-

bolism could only be resolved by complete nitrogen studies such as would be impractical for routine clinical use

With dehydration various constituents of the blood increase in addition to the non-protein nitrogen. Since the blood urea content does not increase in proportion to the loss of fluid, it is evident that the degree of dehydration cannot be determined from the level of the total non-protein nitrogen or any of its constituents. A much better criterion of the degree of dehydration is the increase of total blood protein, erythrocyte count, hemoglobin or hematocrit value. The simplest to use, and probably the most accurate, is the hematocrit value (volume per cent of erythrocytes per 100 c c of blood). A single reading (unless well over normal) is not nearly so valuable as serial studies. By this means, the progression or regression of the dehydration can be quantitatively determined. If there is a possibility of the patient having an anemia or blood loss the total blood proteins could be substituted with advantage.

Blood sodium and blood chlorides should be determined separately, if possible. Few laboratories are equipped to perform routine sodium determinations at present. As previously pointed out, chloride and sodium levels do not always parallel each other. When only blood chlorides are determined, this fact should be kept in mind.

Indirectly, the sodium level can be roughly surmised in many cases from a comparison of the blood chloride level and the carbon dioxide combining power. If the carbon dioxide combining power is high (alkalosis) and the blood chloride level is low, then the sodium level is probably near normal. Conversely a low carbon dioxide combining power (acidosis) with normal or slightly low blood chloride level speaks for the presence of an hyponatremia. This knowledge aids greatly in treating the disturbed electrolyte and fluid balance.

TREATMENT

Rational therapy in instances of this syndrome is necessarily dependent on the determination of the fundamental mechanisms responsible for its production. Due consideration must also be given to the underlying disease process, specific therapy of which may occasionally be available.

In many cases the factors of dehydration and salt deficiency are coincident. The fluid needs of the patient can be roughly calculated from the following program suggested by Collier and Maddock²⁶. The fluid intake should be sufficient to (1) furnish 1500 c c of urine daily, (2) replace abnormal fluid losses such as vomitus, drainage from fistulae, diarrhea, etc., and (3) replace water of evaporation from skin and lungs which amounts to 1000 to 1500 c c daily in uncomplicated cases. With increased heat production, fever, high basal metabolic rate or sweating in hot and humid environments, this loss may amount to 1500 to 3000 c c of fluid per day.

An initial infusion amounting to 6 per cent of the total body weight may safely be given at the beginning of serious dehydration²⁶. Normal saline

is the fluid indicated in most cases. If the patient should be dehydrated, but not suffering from salt loss, 5 per cent glucose in distilled water could be utilized. In severe alkalosis (where the blood sodium is near normal and the chlorides markedly depressed) normal saline may at times fail to correct the electrolyte disturbance. Under such circumstances fluid should be given as isotonic glucose in distilled water and the chlorides supplied by means of ammonium chloride, calcium chloride or even hydrochloric acid. In severe acidosis, where the hyponatremia exceeds the hypochloremia, part of the sodium deficit can be supplied as sodium lactate solution.¹⁰² Where the salt loss greatly exceeds the fluid loss (i.e. in Addison's disease, toxic adrenalitis) it may be necessary to give sodium chloride in addition to that present in physiologic saline. Large oral doses or injection of hypertonic salt solutions is then indicated. Root¹⁰³ calls attention to the fact that anurias which fail to respond to injections of normal saline may do so after the use of hypertonic salt solution.

Fluids may be given orally, intravenously or hypodermically. If the latter method is used, the isotonicity of blood should not be exceeded. It is impossible to give sufficient fluid by rectal instillation alone, although this method can be used to supplement other procedures. Often overlooked is the possibility of giving large volumes of fluid by means of a Levene tube passed into the duodenum and left in place.¹⁰⁴ Some authors believe this to be a better method than the intravenous route.¹⁰⁰ It has the great advantage that nutrient foods can be added to the infused fluid.

In the event of a high non-protein nitrogen due to liver disease the intake of carbohydrates should be increased and the fat and protein diminished. At least 400 grams of carbohydrate are needed daily.

If starvation has been present the protein requirements should be satisfactorily met. Glucose therapy is indicated when acidosis is present.

Where high venous pressure is a factor, specific cardiac therapy and possibly venesection would be of value.

The maintenance of a systolic blood pressure greater than 70 mm of Hg is desired. Blood pressures below this level are usually associated with collapse and shock which must be vigorously treated. The restoration of the normal circulating blood volume will entail intravenous injections of saline, glucose or blood. The patient should be put in "shock position," heat artificially supplied, and oxygen therapy instituted. Strychnine, caffeine, coramine, cardiazol, ephedrine and benzedrine are among the drugs which may be of value. Weiss and Wilkins¹⁰⁵ have recently discussed this aspect of the subject at length.

Where adrenal damage is suspected, and certainly in Addison's disease, the use of adrenal cortical hormone should not be overlooked.¹⁰⁶

In spite of these medical procedures, patients may at times show a progressive increase in azotemia and oliguria, terminating in anuria. This is often due to tubular damage, edema of the kidney or possibly to reflex anuria. There seem to be two surgical procedures which at times may be

valuable. Some striking cures have been reported. The chief obstacle to their use seems to be the lack of any clear cut criteria as to when they are indicated. Few physicians have had any experience with them.

The simplest, and to be tried first, is the sectioning or blocking of the renal sympathetics. This can be done by paravertebral injection of a local anesthetic.¹⁰¹ Cubitt³ has reported excellent results in reflex anuria by the simple procedure of spinal anesthesia. Milliken and Karr⁵¹ favor the use of periaortic sympathectomy.

Where swelling of the kidneys exists bilateral decapsulation may be life saving. Dunn and Dunn¹⁰⁷ have reviewed this subject and offer a remarkable example of such a cure. Such radical procedures should be attempted only under the guidance of an experienced internist and genito-urinary surgeon.

Besides replacement and supportive therapy, every effort should be made to prevent undue loss of fluid and electrolytes. This may mean operation in the case of pyloric obstruction, coagulant therapy in the case of superficial burns, change of environment in the case of excess sweating, repair of fistulae, treatment of diabetes mellitus to relieve polyuria, etc. Such treatment of the underlying disease may prevent the factors causing azotemia from continuing to act. Therapy to relieve azotemia should never be considered to the neglect of such treatment of the underlying disease.

DISCUSSION

To many physicians an elevated blood non-protein nitrogen means kidney disease. It has been our experience on several occasions to meet surgeons who refused to operate on persons with an obstructed pylorus or peritonitis because of an azotemia and the presence of albumin and casts in the urine. These patients were diagnosed as having "kidney disease" or "nephritis" and therefore considered poor operative risks. Such a view is of course not tenable. In routine clinical practice, an azotemia is much more commonly due to the mechanisms discussed in this paper than to organic renal disease. At present, non-protein nitrogen determinations are rarely performed except for persons suspected of having renal disease. Routine and serial blood chemical studies for all the diseases mentioned previously would undoubtedly reveal a striking number of instances of azotemia.

Another common misconception is that the level of the blood non-protein nitrogen in extrarenal azotemia rarely increases to a degree comparable with that seen in organic renal disease. Quite the opposite is true. Values of 100 or even 200 mg per cent are common. Not only may such high figures be observed but frequently they develop within a few days and may disappear as rapidly, if the patient's underlying disease is amenable to treatment. Fishberg⁹⁷ mentions a patient with prerenal azotemia in which the blood non-protein nitrogen increased to 400 mg per cent in three days and diminished in an equally striking fashion following therapy.

The ubiquity of this syndrome should be kept in mind. There are few specialties in which it will not at some time be encountered.

It is hoped that this presentation will aid in clarifying the clinical concept of extrarenal azotemia, though the problem still presents numerous questions to be solved. It is a subject which deserves more attention from the medical profession and which should not be neglected in presenting the problem of renal disease to medical students.

CONCLUSIONS

The syndrome of extrarenal azotemia is present in a wide variety of unrelated and often common diseases. The basic mechanisms producing this syndrome have been analyzed and include (1) Fall in blood pressure, (2) hypochloremia and hyponatremia, (3) dehydration, (4) increased protein catabolism, (5) loss of deaminizing power of the liver, and (6) local renal factors. Reasons are given why cases with tubular damage or edema of the kidney should be included in this syndrome. These mechanisms are interdependent and interrelated and present in varying combinations in different diseases. The relation of the anurias to this syndrome is discussed. Diseases associated with azotemia have been analyzed with this concept in mind. Methods for evaluating the syndrome and consequent procedures for logical treatment have been presented.

Note. Since the preparation of this paper several interesting and pertinent contributions have appeared in the literature. In continuing the search for a toxic substance elaborated in instances of high intestinal obstruction, Scudder, Zwemer and Truszkowski (Surgery, 1937, 1, 74) demonstrated experimentally a resulting rise in blood potassium which attained definite lethal proportions. This suggests the need for further study of the potassium factor in extrarenal uremia. Gomori (Acta med Scandinav, 1937, xii, 497, 503, 515, 1937, xciii, 42) has produced considerably more evidence to substantiate his original views on extrarenal azotemia. Wohl and his co-workers (Jr Lab and Clin Med, 1938, xxiii, 450) have brought forth experimental and clinical data indicating that adrenal damage is often associated with instances of uremia of the extrarenal type. Indeed, as our knowledge of this syndrome increases, the importance of the adrenals becomes more and more impressive. In an exhaustive paper on acute renal pathology, Bell (Am Jr Path, 1937, xiii, 497) has included findings in certain cases in which extrarenal factors had been present. These consisted chiefly of distortion of the convoluted tubules with minor degenerative changes in their lining cells. The influence of these minor pathologic changes on renal function are discussed.

CASE REPORTS

LARGE PERICARDIAL EFFUSION COMPLICATING ACUTE CORONARY THROMBOSIS^{*}

By E. STERLING NICHOL, M.D., F.A.C.P., Miami, Florida

THE clinical features of the pericarditis found during the course of some cases of acute coronary artery thrombosis have been recently reviewed by Blumer¹ who rejuvenated the term *pericarditis epistenocardica* first applied to this condition in 1910 by Sternberg.² In 1872 Baumes³ gave the first clinical picture of *pericarditis epistenocardica*, though he was not aware of the relation of the condition he described to acute coronary artery thrombosis and in fact dubbed the pericarditis "idiopathic." He called attention to the absence of pericardial effusion in his cases. White⁴ comments on the infrequency of pericardial effusion following coronary thrombosis and avers it is of no clinical significance. Levy⁵ states he has never seen effusion in detectable amount associated with coronary thrombosis but in a footnote relates that Herrick has seen one case. Levine⁶ in his recent monograph on heart disease says "Only on very rare occasions is pericardial effusion associated with this type of pericarditis" but does not cite a case in his own experience. Schwartz,⁷ in 1934, was the first to record the clinical detection of pericardial effusion following acute coronary occlusion, his case being that of a man of 50 years who improved after pericardial paracentesis and eventually recovered. Master and Jaffe⁸ reported the following year two cases, both of whom recovered without pericardial paracentesis. These authors believe that pericardial effusion of similar origin must be less rare than the clinical reports published make it appear. The present case is of interest because the effusion was of enough volume to make paracentesis an essential therapeutic procedure and also because following recovery a carcinoma of the cecum was successfully removed.

CASE REPORT

Mr. E. D., a white male of 64 years, with previous good health except for constipation, slight anemia, occasional dyspnea on climbing stairs, and one attack of angina of effort, was stricken on the night of March 6, 1935, with heavy substernal oppressive pain which radiated to the left arm and lasted several hours, relief being obtained only after 30 mg. morphine sulfate were given hypodermically by his physician. Weakness and sweating followed the pain. He was kept at rest, but three days later had a similar attack severe enough to again require 30 mg. of morphine sulfate for relief. The blood pressure was 95 mm. of Hg systolic and 60 diastolic, the pulse weak and the skin moist and cool. The temperature rose during the next few days to 100° F. and a pericardial friction rub was heard on the seventh day, by which time the diagnosis of acute coronary artery thrombosis seemed well established although an electrocardiogram and leukocyte count were lacking. The low grade

^{*} Received for publication July 2, 1937.

fever terminated on the twelfth day, after which time the patient was fairly comfortable until the seventeenth day when the temperature rose to 101° F with the advent of mild substernal pain. He then became weaker and complained of pains through the left chest, so by the end of the third week of his illness, on the occasion of my initial visit, he appeared distressingly ill, was mildly cyanosed and orthopneic. The temperature was 102° F, the pulse soft, rate 124, with sinus arrhythmia, and the blood pressure was 98 systolic and 70 diastolic. Increased venous pressure was indicated by venous pulsation in the neck veins when in the erect position, but no direct measurement was made. The left border of cardiac dullness by percussion extended to the anterior axillary line at the sixth interspace, and the right border was 1 cm beyond the right sternal margin. The apex beat was not located and the heart sounds were somewhat indistinct. There was dullness at the left lung base, with exaggeration of breath sounds, and moist rales at both bases. The liver edge was 3 cm below the right costal border and there was moderate edema of the ankles.

The diagnosis of pericardial effusion following coronary artery thrombosis was suggested. An *electrocardiogram* (3-28-25) revealed slight depression of the RS-T segments in Lead I, with T₁ slightly positive, while conversely in Lead III there were slightly elevated and coved RS-T segments and inverted T-waves. T₂ was inverted. Q and Q₃ were prominent. In Lead IV there was definite elevation of the RS-T segment, and the T-waves did not dip below the isoelectric level. These changes were considered fairly typical of a late Q₃T₃ pattern (this record was made three weeks after the initial episode) indicating infarction, probably in the posterior basal portion of the left ventricle. (Sections of this and subsequent electrocardiograms are depicted in figure 1.)

The hemogram showed red blood cells 3,300,000, white blood cells 9,650, hemoglobin 60 per cent. Neutrophils were 83 per cent, lymphocytes 14 per cent, mononuclears 3 per cent. The blood Kahn and Mueller tests were negative. There were 30 mg non-protein nitrogen and 1.5 mg creatinine per 100 c.c. of blood. A urinalysis was normal.

Radiographic examination (figure 2-A) showed marked general enlargement of the "cardiac" shadow, even after allowing for distortion due to the semi-recumbent position of the patient and a target distance of only 30 inches, and the size and contour were considered suggestive of pericardial effusion. The lung fields showed the changes typical of congestive failure, but otherwise were negative.

Since it was felt that *Heinz-tamponade* accounted for a good part of the patient's discomfort, a needle was inserted below the angle of the left scapula in the seventh interspace and 500 c.c. of amber thin fluid were withdrawn freely from the pericardial sac. The fluid showed 20-35 erythrocytes per field and only 1-3 leukocytes, with lymphocytes predominating on the stained smear. Cultures of the fluid were free from growth after seven days incubation. The improved "cardiac" contour two hours after the paracentesis is shown in figure 2-B, but part of the change was due to the more erect position of the patient and to the fact that this roentgen-ray was made at a distance of 5 feet. The measurements were total transverse "cardiac" diameter 18.5 cm, M R 9 cm, M L 9.5 cm, and internal diameter of chest 30 cm, giving a cardio-thoracic ratio of 60.1 per cent. An *electrocardiogram* made the following day (3-29-35) showed no significant change from the previous record.

Following the pericardial paracentesis the patient was greatly relieved, but owing to the evident congestive failure oxygen therapy, 50 per cent dextrose solutions intravenously and digitalis were employed. The rate of improvement was strikingly indicated when the patient remarked only 12 hours after the paracentesis that "he felt like a new man." The fever disappeared within 48 hours and the following day a direct venous pressure reading was only 10 cm of water. The heart gradually slowed, the blood pressure ranged from 100 systolic and 60 diastolic to 120 systolic

and 80 diastolic, and all signs of congestive failure cleared up at the end of a week. An *electrocardiogram* at this time (4-5-35) showed no essential change.

A small, slightly tender mass was discovered in the right lower quadrant of the abdomen and occult blood was found in the stools. Roentgen-ray examination of the colon revealed a "napkin ring" defect just above the ileocecal valve diagnosed as carcinoma of the cecum.

Improvement in the circulatory state was continuous. A teleoroentgenogram taken five weeks after the paracentesis, on May 11, 1935, showed further decrease in the "cardiac" size, the total transverse "cardiac" diameter measuring 16.5 cm,

FIG 1 Sections of serial electrocardiograms from patient with acute coronary occlusion complicated by pericardial effusion. The first curve taken three weeks after onset of attack, dated 3-28-35, shows a late Q-T pattern indicating infarction in the posterior basal portion of the left ventricle. No appreciable change is noted in the next curve taken the following day, in spite of fact that 500 c.c. of pericardial fluid had been removed. On 5-11-35 little change is noted in the electrocardiogram, although by this time all clinical signs of pericardial involvement had vanished, indicating the initial alterations were due to coronary occlusion rather than the complicating pericarditis. The curve of 11-6-35, showing some increase in voltage of the ventricular complexes, was taken just prior to resection of carcinoma of the cecum, while the last curve, taken 2-15-36, was after complete recovery from this operation (Lead IV, made with right arm electrode over fourth left interspace, the left leg electrode serving as indifferent electrode).

MR 6.5 cm, ML 10 cm, giving a cardio-thoracic ratio of 55 per cent (Figure 3-A). An *electrocardiogram* on the same date showed no significant change except that in Lead IV, the RS-T segments were no longer elevated and T₄ was now inverted. The patient was permitted gradually to be up and about, and, ten weeks after the onset of his attack, was able to go north where his strength and weight further improved, and roentgenologic reexamination of the colon showed no demonstrable increase in the carcinoma. On his return south the following November there were no physical signs of heart disease, the blood pressure was 135 systolic and 80 diastolic, and the

heart appeared, on fluoroscopy, to be of normal size and contour. An *electrocardiogram* at this time showed improved voltage, T_1 frankly positive and deeper inversion of T_4 .

As his recovery now seemed maximal, laparotomy was performed under spinal anesthesia, by Drs J W Snyder and J C Turner. An adenocarcinoma of the cecum (grade 2) was found without malignant fixation of the parietes, or any glandular, pelvic shelf, or liver involvement demonstrable. Resection of the cecum and part of the ascending colon was followed by a Wetzel enterostomy proximal to an end to side anastomosis. A direct transfusion of 500 cc of blood successfully overcame the moderate shock produced. The post-operative course was noteworthy for its smoothness, there being an average amount of abdominal discomfort, but no circulatory symptoms other than occasional mild precordial pains. The enterostomy wound eventually closed, and the patient was up and about within a few weeks.

FIG 2 Heart films made with portable equipment. A—taken 3-27-35, patient semi-recumbent, 30 inch distance, 3 weeks after acute coronary thrombosis, showing pericardial effusion. B—taken the following day, 2 hours after withdrawal of 500 cc of pericardial fluid, erect position, 5 ft distance, transverse "cardiac" diameter 18.5 cm, internal chest diameter 30 cm, CT ratio 60 per cent.

A *teleroentgenogram* on February 15, 1936, nearly a year after the acute episode (figure 3-B), disclosed a normal cardio-thoracic ratio of 49.3 per cent (total transverse cardiac diameter 14.8 cm, MR 5.3 cm, internal diameter of the chest 30 cm). An *electrocardiogram* the same day showed little change from the previous record. The patient was last seen in April 1937 and felt very well except for moderate fatigue and occasional vertigo. He had gained 25 pounds (11.3 kg) in weight, and was able to walk two miles a day without discomfort. The *electrocardiogram* at this time showed no further change.

IN REGARD TO ELECTROCARDIOGRAPHIC SIGNS OF PERICARDITIS

The changes in the *electrocardiogram* produced by *uncomplicated pericarditis*, with or without effusion, have been fully described recently by Schwab and Heirman.⁹ Their conclusions, based on a review of the relevant literature

since the observations of Oppenheimer and Mann¹⁰ in 1923, together with their own study of serial electrocardiograms in seven cases of pericardial disease, may be summed up as follows. The usual *early* alterations consist of low voltage of the ventricular complexes and elevation (never depression) of the RS-T segments in Leads I and II or all three conventional leads, although these changes may be lacking. The usual *late* alteration consists of inversion of the T-waves in the same leads, either following the regression of the RS-T segments to the isoelectric level, or appearing without preceding RS-T segment elevation. In the few instances where Lead IV was taken slight deviation in the RS-T segments and positive or biphasic T-waves were revealed. Although mimicking the electrocardiogram following acute coronary occlusion, pericardial disease is differentiated by the *absence* of reciprocal relationship in the RS-T

FIG 3 Teleoroentgenograms of the same patient. A—taken 5 weeks after the paracentesis showing further decrease in "cardiac" size. Transverse "cardiac" diameter 16.5 cm, internal diameter of chest 30 cm, CT ratio 55 per cent. B—taken 7 months after A, and 3 months after resection of the colon. The transverse "cardiac" diameter is 14.8 cm, CT ratio 49.3 per cent or normal.

deviations and T-waves in Leads I and III, and by the *absence* of abnormal Q-waves. Serial electrocardiograms show that as the pericarditis heals the T-waves gradually become positive again.

The typical electrocardiographic pattern in *acute coronary occlusion complicated by pericarditis* is featured, according to a recent study made by Baines,¹¹ by elevation or dome-shaped upward rounding of the RS-T segment in all three conventional leads, without the reciprocal depression of the RS-T segment either in Leads I or III characteristic of myocardial infarction. This change is followed by inversion of the T-wave in all conventional leads, or in some instances by a T-pattern typical of late coronary occlusion. Even early, however, the Q-pattern may be so typically developed that myocardial infarction, and its location, is indicated. In other words, this author holds that if acute coronary occlusion is attended by pericarditis, the characteristic early reciprocal deviation

in the RS-T segments in Lead I and III is overshadowed by the signs of pericarditis, i.e. elevation or dome-shaped upward rounding of the RS-T segments in all three leads, the only intact evidence of infarction in the early stage being the characteristic Q-pattern. There was no clinical evidence of pericardial effusion in the cases comprising Barnes' study.

In the case under discussion, proof that the first electrocardiographic changes were due to acute coronary occlusion (of 21 days' duration) rather than to the pericarditis, rests on the lack of electrocardiographic improvement following the disappearance of the clinical signs of pericarditis. Granting this, the retention of the characteristic late reciprocal relationship of the RS-T segments and T-waves in Leads I and III together with a typical Q_s pattern, suggests that pericarditis even with effusion does not appreciably alter the electrocardiographic pattern induced by acute coronary occlusion if the infarction is in the posterior basal portion of the ventricle.

The electrocardiographic pattern in this case, however, need not be taken to controvert the above conclusions of Barnes¹¹ for of the eight cases studied by that author seven were eventually shown to have anterior or apical infarction in the left ventricle, and the remaining case suggesting posterior basal infarction did not show exactly typical changes in the electrocardiogram, and may have been an instance of combined posterior and anterior infarction of the left ventricle, as pointed out by the author, since no friction rub was heard and autopsy was lacking. It is quite likely in view of the foregoing, that the electrocardiographic pattern noted by Barnes is typical only of anterior or apical infarction in the left ventricle complicated by pericarditis, and it may eventually be shown in additional cases that the characteristic electrocardiographic pattern of infarction of the posterior basal portion of the left ventricle is not overshadowed by the advent of pericarditis.

SUMMARY

A case of acute coronary thrombosis with massive pericardial effusion necessitating paracentesis has been described. This case was further complicated by adeno-carcinoma of the cecum found during convalescence and later resected successfully.

The electrocardiographic signs of pericarditis, including *pericarditis episteno-cardica*, have been briefly reviewed. The study of serial electrocardiograms taken in the present case suggests that when infarction of the posterior basal portion of the left ventricle is complicated by pericarditis, the electrocardiographic signs of this complication will be lacking, in contra-distinction to the electrocardiographic pattern observed when pericarditis follows infarction of the anterior or apical portion of the left ventricle.

Note. When preparing this report I overlooked the article of Wolterth and Wood (Arch Int Med, 1935, 61, 77) in which they showed that electrocardiograms similar to those depicted by Barnes may be due to infarction involving both the anterior and posterior surfaces of the left ventricle.

Recently Vanderveer and Norris (Am Heart J, 1937, 14, 31) have adduced evidence that the electrocardiographic changes in pericarditis are the result of superficial myocarditis associated with the pericarditis.

The patient described in this case report is free from all complaint at present, three years after the onset of his attack. His electrocardiogram shows no change from the last one illustrated.

HYPERINSULINISM ASSOCIATED WITH HYPOTHYROIDISM TWO CASE REPORTS

By JOHN L. CARMICHAEL, M.D., *Birmingham, Alabama*

THE following cases are reported because the findings indicate that there may be a cause and effect relationship between hypothyroidism and hyperinsulinism or at least that hypothyroidism may aggravate hyperinsulinism. Considerable experimental work has indicated a definite interrelationship between the secretion of the thyroid and that of the islet portion of the pancreas. It has been shown also clinically, that the injection of insulin changes the basal metabolic rate, but in a review of the literature available to us, no case report has been found indicating a definite relationship between hyperinsulinism and hypothyroidism. Tedstrom,¹ however, reports a case with a hyperinsulinism type of blood sugar curve in which the basal metabolism reading was minus 22. He states that the basal metabolic rate was increased to normal with thyroid extract without relieving any symptoms except that of headaches. He does not indicate, however, that the glucose tolerance test was repeated while the metabolism was at a normal rate.

Marine² reports Falta as believing that the thyroid and pancreas are antagonistic. Falta found that thyroidectomized dogs were less sensitive to the hyperglycemic action of epinephrine than normal animals. This, so Marine states,

* Received for publication May 29, 1937.

has been confirmed by Bodansky and by Burns and Marks. Bodansky reported that thyroidectomized sheep were more sensitive to insulin than normal animals. Marine also is authority for the statement that thyroid or thyroxine fed to thyroidectomized rabbits decreases the hypoglycemic action of insulin.

Simnitzky and Komendantowa³ by rather extensive histological studies on animals found that the continued injection of insulin produces a diminution of the function of the thyroid which manifests itself morphologically in the flattening of the epithelium lining the walls of the acini and in a retention of the colloid in the acini.

Ernst and Kaufman⁴ gave one gram of dextrose per kilogram of body weight to 11 patients suffering from various diseases. They then gave one-fifteenth of a unit of insulin per kilogram of body weight to each patient and recorded blood sugar readings at 20 minute intervals.

After the ingestion of the dextrose and the injection of insulin the average increase of blood sugar reading was as follows: After 20 minutes 34.7, after 40 minutes 45.5, after 60 minutes 44, and after 80 minutes 38.7. The same procedure carried out on a small group of patients suffering from Basedow's disease and from hyperthyroidism gave the following average increases in blood sugar readings: After 20 minutes 41.1, after 40 minutes 51.7, after 60 minutes 54.4, and after 80 minutes 47.6. This clinical experimental work, as will be observed, indicates that increased activity of the thyroid inhibits to some extent the action of insulin so that the blood sugar rises higher after dextrose is given in the hyperthyroid and exophthalmic goiter cases than in those whose thyroid function is less active.

These latter observations are also in accordance with the observations of those clinicians who have noted that in cases of diabetes associated with hyperthyroidism the surgical treatment of the hyperthyroidism lessens the severity of the diabetes. Apparently the removal of an excess of thyroid secretion allows the production of more insulin.

The following cases add further evidence tending to substantiate the observations outlined above and suggest a treatment for some cases of hyperinsulinism other than diet and surgery.

CASE REPORTS

Case 1 E. C. H., white, male, aged 36, a bookkeeper, was admitted to the Birmingham Baptist Hospital on December 25, 1935, and was first seen by me shortly afterward. His wife gave the history that she had been awakened about 3:00 a. m. and had found the patient in a convulsion during which he foamed at the mouth and bit his tongue to the extent that the froth was quite bloody. He was unconscious for about 30 minutes after she awakened, but seemed normal after consciousness returned. He was admitted to the hospital about one-half hour after regaining consciousness.

When I first saw him, a few minutes after his admission, he was rational and comfortable except for a slight headache. He did not recall anything immediately preceding the convulsion. Physical examination revealed a well developed and well nourished young man apparently relaxed and comfortable in bed. He was well oriented. Nothing abnormal on physical examination was found except a swollen and slightly lacerated tongue. Pupils were equal and symmetrical and responded to light. Patellar, biceps and abdominal reflexes were normal. The Babinski sign was not present.

Past history was irrelevant except that he had awakened one morning several weeks before with a sore and swollen tongue. He also stated that he had great difficulty keeping awake at times and had, on one occasion, fallen asleep while driving his car.

His family history was irrelevant except that one sister had diabetes and one niece had exophthalmic goiter.

Routine laboratory examination on admission was negative. A spinal puncture was done some hours after admission. This revealed the spinal fluid under normal pressure. Seven cells were found per cubic millimeter and there was a trace of

FIG 1 Case 1

globulin. The Wassermann was negative. A fasting blood sugar determination a few hours after his admission was 108 mg per 100 c c of blood.

A few days later a glucose tolerance test was done. After a redetermination of the fasting blood sugar the patient ingested 100 grams of glucose and hourly blood sugar readings were taken for four hours. His fasting blood sugar was 87 mg per 100 c c, after one hour it was 137, after two hours 120, after three hours 68, and after four hours 42, as shown in figure 1. A basal metabolic reading taken immediately before the ingestion of glucose gave on two tests minus 15 each time. The patient was put on three grains of desiccated thyroid gland which he took daily, with

rest intervals, until four and one-half months later. The basal metabolism reading at this time was plus 36. A glucose tolerance test on the following day gave the following results, as shown in figure 1. The fasting blood sugar was 87 mg per 100 c.c., after one hour 127, after two hours 77, after three hours 80, and after four hours 75. This suggests that the increased utilization of thyroid secretion in the body had depressed the production of insulin so that the blood sugar had remained higher and thereby prevented further convulsions. Until this date the patient has had no further convulsions.

Case 2 C. V., white, male, aged 39, locomotive fireman, was seen at the office on June 30, 1936. His chief complaint was of recurring attacks of convulsive seizures which were accompanied by loss of consciousness. The first one had occurred on July 27, 1935. The attacks, he stated, usually started with twitching of the muscles of the right side of the face and a bending of the body over to the right side. They were preceded by cold chills up and down the spine and a feeling of lightness in the head. He had noticed that the attacks had always occurred when he had gone without food for an unusually long time. His friends had told him that the convulsive twitching became generalized over his body and that he would remain unconscious for 10 or 15 minutes. He states that for 20 or so additional minutes he would be disoriented and unable to talk. There had been probably 15 or 20 such attacks before the consultation on June 30, 1936. The last one had occurred five days previous to his visit to the office. He stated that in addition to those attacks he had had a rather marked loss of memory for recent events. Past history and family history were irrelevant except that his father had been excessively overweight.

Physical examination at this time revealed a well developed and overweight white male, 66½ inches in height and weighing 234 pounds. Nothing else abnormal was found on physical examination. The laboratory examination including a fasting blood sugar was normal except that the basal metabolism reading was minus 20. A glucose tolerance test, however, gave the following results: Fasting blood sugar 85 mg per cent, first hour after 100 grams of glucose 128, second hour 112, third hour 55, and fourth hour 56 mg per 100 c.c. of blood. It will be noted that a low of 55 mg per 100 c.c. of blood occurred three hours after the ingestion of the glucose.

Experience with the previous case caused us to try to control the hyperinsulinism by increasing the metabolic reading to normal with thyroid extract. Accordingly we put this patient on four grains of thyroid daily. On July 23 the basal metabolism reading was minus 38. At this time the glucose tolerance test was repeated with results as follows, as shown in figure 2: Fasting blood sugar 92, first hour after glucose 174, second hour 124, third hour 84, fourth hour 80, fifth hour 88, and sixth hour 92 mg per 100 c.c. of blood. The patient had continued to have occasional attacks so we increased the thyroid dosage to 5 grains daily and on August 12, about three weeks later, we repeated the basal metabolism reading and the glucose tolerance test. The basal metabolism reading was plus 7.5 and the glucose tolerance test was as follows (figure 2): Fasting blood sugar 92, first hour after glucose 184, second hour 141, third hour 95, fourth hour 65, fifth hour 78, and sixth hour 90 mg per 100 c.c. of blood.

In spite of this change in glucose tolerance the patient reported that he was having still occasional attacks of the same type of convulsive seizure. They were, however, not so numerous and he felt much better than he had felt previously.

We had allowed him to manage his diet as he chose. We inquired of him what his diet was and he explained that he had been visiting with friends and relatives and eating a great deal of pies and cakes and other carbohydrates. We felt, however, now that we would not be able entirely to control the attacks with thyroid extract. We therefore placed him on a high fat and low carbohydrate diet, as has been sug-

gested by Harris⁵ This he has followed now for about two and one-half months with only one such attack We obtained the history in regard to this attack that he had eaten a heavy meal one evening and had taken a purgative that evening and the morning after The attack occurred at the noonday meal the day following the indiscretion in diet A further follow-up on this case indicates that he still has an occasional attack

FIG 2 Case 2

SUMMARY

- 1 The literature is briefly reviewed and an indication of mutual antagonism between the thyroid and islet secretions is noted No attempt is made to determine whether the antagonism is direct or through the intermediary of some gland such as the pituitary
- 2 Case reports of hyperinsulinism associated with hypothyroidism are given
- 3 The effect on the hyperinsulinism curve of the feeding of desiccated thyroid is noted Further progress of the cases under thyroid medication is given This follow-up indicates that some cases of hyperinsulinism may be improved if not held entirely in check by the use of desiccated thyroid gland It is realized, however, that results of such treatment in a large number of cases followed over a much longer period of time would be necessary before any trustworthy conclusions could be drawn

MUSCULO-SPIRAL PARALYSIS AFTER SERUM INJECTION (RECURRING AFTER SECOND INJECTION)

By LEOPOLD BRAHDY, *New York, N Y*

L D, a hospital orderly 25 years of age, was using alcohol in excess. He had never been in any occupation which could have exposed him to lead. On February 24, 1934, he was given 1500 units of tetanus anti-toxin because of a laceration of the sole of the foot. One week later, he complained of severe pain in the neck and in both arms. Examination showed the muscles of the arms tender and in some degree of spasm. The diagnosis of polyneuritis was made. On April 3, examination showed left wrist drop, no anesthesia. The wrist drop persisted several months and finally disappeared, leaving no residual signs or symptoms. In August 1934, he was admitted to the hospital for two days for acute alcoholism. No abnormality of the extremities was noted at that time.

In 1934, he had a lobar pneumonia. No serum was used and he made an uneventful recovery.

On August 22, 1935 he was pinched over the dorsum of the elbow by a patient suffering from cerebro-spinal meningitis. There was no open wound. However, another orderly (J G) had been scratched by this same patient several days before and had developed gas bacillus infection from the scratch. This fact frightened L D and he requested and was given "1500 units of tetanus anti-toxin and a prophylactic dose of gas gangrene bacillus" serum. This injection was given subcutaneously in the left upper arm. He is quite certain that there was no intramuscular injection. He had no symptoms until eight hours later when he developed pains in the left arm radiating from the spine to the fingers. Two days later, he noticed left wrist drop. There was no urticaria nor any other anaphylactic symptoms. Physiotherapy treatments were administered for several months, but the wrist drop persisted.

Since the patient is well acquainted with medical procedures, his statement that the injection was subcutaneous is more reliable than would be that of another layman. In spite of that history, we considered the possibility of direct nerve injury. The absence of any pain, weakness or numbness, however, until eight hours after injury, was entirely inconsistent with this hypothesis.

In November 1935, he was readmitted for three days for acute alcoholism.

* Received for publication May 13, 1937

Twenty months after the onset of the second wrist drop, examination by Dr Byron T Stookey at the Neurological Institute was reported in part, as follows

"The neurological examination is entirely negative except for the presence of rather lively but equal reflexes of both lower extremities and the right upper. The left upper reflexes, supplied by the seventh cervical, namely, the triceps and the ulnar, are diminished. The ulnar jerk is absent on the left side and is present on the right. There is definite atrophy of the extensors of the fingers of the left hand. The *supinator longus* contracts, as does also the *brachia radialis longus* and *brevis*, but there is no extension of the fingers or of the thumb. In short, this patient has evidence of a wrist drop which has in part recovered sufficiently to permit part extension of the wrist but no recovery has taken place in the extensors of the fingers or the thumb."

In 1932, Wilson and Hadden¹ reviewed cases of peripheral nerve lesions after serum injection, and in 1933 Wulf² reported nerve lesions after serum injection. There is no case reported of transient paralysis with recurrence of the paralysis in the same nerve after a second injection. We have here a case of paralysis (now permanent) recurring after a second injection. Excessive alcoholism may have rendered the peripheral nerves susceptible. Although I have seen many hundreds of patients who had prophylactic or therapeutic serum injections, this is the only one resulting in any permanent defect. I believe that we may accept Wulf's statement to the effect that disturbance of the nervous system is so rare that it does not limit the indications for the use of serum.

EDITORIAL

THE PRESIDENTIAL ADDRESS

THE Presidential address of Dr James Howard Means at the Convocation of the College attracted unusual attention. The membership of the College will have the opportunity of reading the full text of this able speech in the May issue of the *ANNALS*. However, because of the misinterpretation of certain of Dr Means' remarks it has seemed advisable to the Regents that in this issue there should appear a statement addressed to the membership of the College and to the general medical profession.

In some quarters it was apparently thought that Dr Means had called upon the medical profession to revolt against the leadership of the American Medical Association. Indeed, it was suggested that under certain conditions the College should take away from the American Medical Association the function of representing the medical profession. Naturally 'such statements have not failed to be disturbing to those of our Fellows who did not hear Dr Means' address.

In his remarks Dr Means was critical of the recent policy of the American Medical Association which he summarized as standpatism. He expressed himself as believing that since the organization of the American Medical Association is that of a democracy it would be in a healthier state if it always contained, in addition to the existing administration, an effective opposition party so that there might be active discussion of vital issues. He felt that it was desirable that those who believe in popular government should bestir themselves to bring this about.

It is no more a revolt against the American Medical Association to criticize its present policy and to suggest that within its membership an effective opposition should be organized, than it is revolt against the United States for one of its citizens to criticize the New Deal and to express a fervent wish for a successful opposition party.

Dr Means made it very plain that he was not giving voice to a policy, nor to a political program of the College, for in his analysis of the purpose of a college of physicians he stated his opinion as follows: "I have said what I have said in order to indicate what I conceive to be the fundamental difference between a college of physicians and a national or state medical society. Each has its use but they are different. The college is not in competition with the medical association. The college should be a counterpart of the university, not that of the state. It should be as unthinkable for us to have a College policy regarding social, economic, political or scientific aspects of medicine as for one of our universities to take sides in a political campaign. It should also be unthinkable that we should at any time be unwilling to hear all sides of any problem related to the practice of medicine."

It is evident therefore that Dr Means, believing as he does that the College should be a body without a policy, was expressing only personal views concerning the advisability of an opposition party in the American Medical Association, and least of all was he presaging a future supplanting of the Association by the College

The interpretations to which we have referred are therefore quite unwarranted by the content of Dr Means' speech

Because of the questions raised by this incident the following account of the position taken by the Officers and Regents of the College in the past may be of interest

Among the Objects of the College mentioned in the Constitution (Article III, Sec 1a) is that of "maintaining and advancing the highest possible standards in medical education, medical practice and clinical research" Since the Officers and Regents are empowered to represent and to act for the College in matters defined in the Constitution and the By-Laws the above section would permit the Officers and Regents by formal motion recorded in their minutes to commit the College to any policy or action which in their opinion would further these objects However, up to this time the conception of the proper rôle for the College has been in accord with Dr Means' definition The College has not felt that it should have any policy other than that of the ethical principles embodied in its Fellowship Pledge It has so far followed a precedent of holding aloof from any official action, or pronouncement of opinion bearing upon disputed questions of medical practice It has become customary to refer inquiries, requests for opinions, etc on such matters to the Committee on Public Relations who submit a report to the Board of Regents The Board of Regents has up to this time consistently stated that the College was not committed to any policy and that its function was not that of serving as an arbiter It seems highly probable that this precedent will continue in force It seems certain, moreover, that should some future emergency in the affairs of the medical profession induce the Officers and the Regents of the College to attempt to marshall the strength of its membership in defense of some vital principle, a first step, before pronouncing a College policy in any contentious question, would be to submit the proposal to the vote of the Fellows of the College in a General Meeting

The College has been and is unreservedly devoted to the principle of free speech The more vital and the more controversial a topic is, the more important it is that the members of the College should hear the best obtainable presentation of both sides The College will keep its meetings open to the expression of any sincere opinion upon any side of any medical problem Nor does the College intend to taboo any subject from discussion by its own Fellows, Masters, Governors, Regents or Officers

It should be plain to the membership, however, that no statement by any one of these constitutes a College policy

REVIEWS

Arteriovenous Aneurysm By EMILIE HOLMAN, M D 244 pages, 15 × 22 cm The Macmillan Co, New York 1937 Price, \$5 00

This recent book by Holman justly deserved the recognition given when it was awarded the Samuel D Gross prize by the Philadelphia Academy of Surgeons. The first part of the book deals with experimental work and if studied carefully yields clearer understanding of the physiological adjustments to the presence of arteriovenous fistulae. The author then discusses in detail both congenital and acquired arteriovenous fistulae and aneurysms of the extremities and other parts of the body. This portion of the book is a most excellent summary of recent clinical investigations of these conditions.

The book on the whole is a splendid piece of work from the experimental, clinical and historical points of view. It will prove to be of value to the teacher, both of medicine and of surgery, and especially to the research worker in this field.

T B A

Radiation Therapy By IRA I KAPLAN 558 pages, 16 × 24 cm Oxford University Press, New York 1937 Price, \$10 00

This volume will be of interest to the internists as well as to those treating disease by means of radium and roentgen-rays. It is written from a practical viewpoint. Dr Kaplan's wide experience in radiation therapy is evident in every chapter. The chapter on physics by Braestrup is unusually clear so as to be readily understandable to any physician. The illustrations are excellent and the extensive bibliography will be helpful to students. The subject cannot be fully covered in one volume and certain chapters, notably those on radiation therapy in neurological disease, inflammatory processes and bone diseases, seem too brief to be adequate. It can be recommended as an excellent reference on radiotherapy.

W L K

Medical Greek and Latin at a Glance By WALTER R AGARD Second edition revised 87 pages, 16 × 25 cm Paul B Hoeber, Inc, New York 1937 Price, \$1 50

This little volume will prove of real help in understanding many of the terms in our bilingual medical nomenclature. It is really a glossary and makes plain the derivation and meaning of many words to those who have little Latin and less Greek. It meets a real need.

L A M K

Essentials of Psychiatry By GEORGE W HENRY, M D, Associate Professor of Psychiatry, Cornell University Medical College, New York City 465 pages, 15 × 24 cm The Williams and Wilkins Company, Baltimore 1938 Price, \$5 00

This is the third edition of a very well known book, which has gained popularity because it presents the essentials of psychiatry in understandable language. This specialty has made rapid progress, and Dr Henry has brought his book up to date.

In his twenty chapters the author has steadfastly held to his conclusion that psychiatry is as scientific as any other branch of medicine, and that in its practice it is necessary for the physician to take all of the facts regarding illness into consideration. "There is no short road to the understanding of human reactions and it is

only after years of training and experience that the physician is prepared to deal adequately with personality disorders"

The first ten chapters discuss the development of the personality and its disorders. Dr. Henry clearly describes the various types of psychopathology, discussing each classification in the following order: definition, frequency, causes, symptoms, types, course of illness, prognosis, excerpts from illustrative cases, and discussion of the classification.

The last ten chapters take up method and purpose of mental examination, principles of treatment, psychiatric nursing, psychopathology of the normal, mental hygiene, disorders of childhood, psychiatric social service, medico-legal aspects, psychiatric history, and milestones in psychiatric history.

J. L. McC

Practical Talks on Kidney Disease By EDWARD WEISS, M.D., Professor of Clinical Medicine, Temple University School of Medicine. 176 pages. 14.5 × 22 cm. Charles C. Thomas, Springfield and Baltimore. 1937. Price, \$3.00.

This small volume makes no pretensions to being an exhaustive treatise on the subject of renal disease. The title is well chosen. Nevertheless, it contains the essential information presented in a readable fashion. There are brief chapters on the physiology of the kidney, impairment of renal function, and tests of renal function. The author then presents the principal signs and symptoms of renal disease and devotes short chapters to the more important ones such as edema, albuminuria, hypertension, retinal lesions (illustrated), etc. The various clinical syndromes and their treatment are then described. Part VII deals with hypertension and the rôle it may play in kidney disease.

Those who have made a particular study of this field probably will gain nothing new from this book. The reviewer recommends it to practitioners and students.

W. S. L., Jr.

Physical Diagnosis By RALPH MAJOR, M.D., Professor of Medicine in the University of Kansas. 457 pages, 15.5 × 24 cm. W. B. Saunders Co., Philadelphia. 1937. Price, \$5.00.

This textbook is a comprehensive survey of physical diagnosis. It includes chapters on all parts and all systems of the body, with two additional, one on pain and the other on history taking.

Dr. Major includes so much information, with so many interesting and important little details, that the result is at times confusing. This is obviated to a certain extent by the splendid illustrations, both photographs and diagrams which help to elucidate the text.

Those interested in Dr. Major's former book, "Classic Descriptions of Disease," will be pleased to know that the subject is approached as much as is possible from an historical point of view. Besides the introductory chapter, with its accounts of some of the great personages in medicine, the text includes many original descriptions of disease and some original illustrations.

The clinical side of physical diagnosis is stressed, but one wishes that a little more space had been given to those chapters dealing with diseases of the heart and lungs. The chapter on the pulse, however, is excellent and, but for the omission of any mention of auricular flutter, might serve as a standard for instructors in physical diagnosis.

The usefulness of the book is enhanced by the splendid bibliographies that the author has appended to each chapter.

R. A. R.

Alcohol One Man's Meat By EDWARD A. STRECKER, M.D., and FRANCIS T. CHAMBERS, JR., M.D. 230 pages, 14 × 21 cm Macmillan Co., New York 1938 Price, \$2.50

This volume dealing with "Another Man's Poison" constitutes an excellent graduate course on how to handle chronic alcoholics. From cover to cover it is packed with interesting information concerning the physiology and toxicology of alcohol, the psychology and pseudo-philosophy of the alcoholic patient and the ways and means for the intensive psychical reeducation of the victim of alcoholism. No thinking physician can read it without deepening his understanding of the problems of alcoholism and increasing his ability to cope with them, for the treatment suggested is directed not so much to the disease itself as to its underlying causes.

The authors question the stimulating action of alcohol and regard its effect rather as that of a camouflaged narcotic, the deception of stimulation arising from the release of the lower nerve centers from the control of the higher by its narcotizing power. Alcohol is used commonly by the laity because it is the only narcotic that can be purchased inexpensively in a glass or bottle and without a doctor's prescription. It is used as a salve to the ego as, in the beginning at least, it acts magically in soothing the painful wounds of personal belittlements and feelings of insignificance.

The authors differentiate normal from abnormal drinkers. The normal drinker uses alcohol in moderate amounts as a socially accepted gesture and for purposes of conviviality and rarely gets into trouble from it. Through its use the adult attains temporarily a childlike state of mind and freedom from the behaviorism demanded by maturity. Such a one drinks to exaggerate reality because he finds reality enjoyable. The border line between normal and abnormal drinking is crossed when alcohol is used as an aid in the adjustment to reality. The abnormal drinker is the individual who cannot face reality without alcohol, but whose adequate adjustment to reality is impossible as long as he uses alcohol. In other words the abnormal drinker is an abnormal individual seeking release from reality through the medium of alcohol. Treatment of alcoholism therefore involves the management of an abnormal personality. The authors take their cues for treatment from the psychotherapists who have led their neurotic patients suffering from neurasthenia, anxiety states, hysteria or compulsive neuroses back to the normal planes of life. Many of the procedures used in these various disturbed psychical states are equally effective in the management of the chronic alcoholic.

The authors believe that the psychoneurosis which is responsible for much of our alcoholism must be traced back to its causes and these must be met by appropriate psychotherapy. The underlying neuroses are due most frequently to unfavorable early home life, constitutional predisposition, or to chronic disease, sex conflicts, financial difficulties, restricted outlets or actual mental defects.

According to the authors, treatment should not be started while the patient is still drinking, in fact not until the patient sees his own need, seeks help on his own initiative without outside persuasion or coercion, and is willing and eager to participate in his own cure. The psychotherapist should not undertake treatment until he is convinced that it is possible to bring about a state of mind in his patient that desires not to drink any more. The patient must understand in the beginning that it is impossible for him ever to learn to drink in moderation. He must be willing to face life without alcohol. The treatment advised, consists of prescribed rules and schedules, psychological treatments, mental reeducation and physical adjustments. The patient must be carried from lower to higher and mature levels, must be taught his own needs, gain an insight into his crippled condition and taught how to help to cure himself. He must practice abstinence throughout the period of management. The treatment usually necessitates at least one year of supervision and in all about one hundred conferences with the psychotherapist.

The reviewer believes that this book constitutes a real contribution to medicine. The treatment as outlined seems ideal for the more intelligent and tractable alcoholics, especially if enthusiastically applied by a properly qualified psychotherapist. Whether or not this or any other system of treatment will meet the needs of the average and less intelligent drunkard is open to question. Certainly it would not appear to be more costly or time consuming than present methods of management which entail long or frequent and intermittent hospitalization.

Dr Matthew Molitch (Associate), Philadelphia, Pa—twenty-nine reprints,
Dr Eugene S Sugg (Associate), New York, N Y—one reprint

REGIONAL MEETING OF KANSAS MEMBERS

Members of the American College of Physicians resident in the State of Kansas held their annual meeting and dinner in Wichita, under the Governorship of Dr Thomas T Holt, February 22, 1938 The following program was rendered

- "Treatment of Cardiacs with Oscillator Bed," Dr Harold H Jones (Fellow),
Winfield, Kan ,
- "Medical Problems in Mineral Metabolism," Dr Frances Helen Schiltz (Fellow),
Wichita, Kan ,
- "Peptic Ulcer, Carcinoma Question," Dr H N Tihen (Fellow), Wichita, Kan ,
- "Use of Insulin in Mental Disease," Dr D V Conwell (Associate), Halstead, Kan ,
- "Insulin in Treatment of Schizophrenia," Dr R M Fellows (Fellow), Osawatomie,
Kan ,
- "Cerebral Spinal Pressure Relative to Blood and Circulatory Disturbance," Dr
Thomas T Holt (Fellow and Governor for the State of Kansas), Wichita, Kan ,
- "Simmond's Disease (Pituitary Cachexia)," Dr G F Corrigan (Associate)
Wichita, Kan ,
- "Clinical Phases of Recent Developments in Connection with the More Modern De-
velopments in Cancer Etiology," Dr P M Krall (Associate), Kansas City
Kan

Dr E J G Beardsley (Fellow and Governor for Eastern Pennsylvania), Philadelphia, Pa, spoke on "Medical Conditions Which Simulate Abdominal Emergencies" at the University of North Carolina's Postgraduate Seminar, held at High Point, N C, March 17, 1938

Dr Beardsley also held a morning and afternoon medical clinic at the Sacred Heart Hospital, Allentown, Pa, on March 24 1938

Dr Claude Ellis Forkner (Fellow), who has just completed a five-year appointment as Associate Professor of Medicine in the Peking Union Medical College, has returned to New York and has been appointed Assistant Professor of Clinical Medicine at Cornell Medical School Dr Forkner has also been appointed Assistant Attending Physician at the New York Hospital, and has opened an office for the practice of Internal Medicine and Hematology at 121 East 60th Street, New York, N Y

Dr Paul H Ringer (Fellow), Asheville, N C, has been made President of the Southern Tuberculosis Conference

Dr Charles S Holbrook (Fellow), New Orleans, La, has been made President-Elect of the Southern Psychiatric Association

Dr Paul D White (Fellow), Boston, Mass, addressed the North Side Branch of the Chicago Medical Society, recently, on "Nature, Diagnosis and Treatment of Heart Disease"

The second annual New Orleans Graduate Medical Assembly was held in New Orleans, March 7 to 10 Fellows of the College who participated on the program were Dr Reginald Fitz, Boston and Dr Udo J Wile, Ann Arbor Mich

The tenth annual spring clinical conference of the Dallas Southern Clinical Society was held at Dallas, Tex, March 14 to 17 Guest speakers and their subjects were Dr Russell L Haden (Fellow), Cleveland, Ohio, "Treatment of Arthritis," and Dr Howard T Karsner (Fellow), Cleveland, Ohio, "Research on Hypertension"

Dr Walter P Gardner (Fellow), Hastings, Minn, has been made Superintendent of the Anoka State Hospital

Dr Wallace M Yater (Fellow and Governor for the District of Columbia), Professor of Medicine, Georgetown University School of Medicine, Washington, D C, delivered the annual Kober Lecture at the University March 28 His subject was "Goiter and the Heart An Exposition of the Present Status of Our Knowledge of the Subject, Including Original Research Work in This Field"

Dr Carl J Wiggers (Fellow), Cleveland, Ohio, spoke on "The Dynamics of Hypertension" before the annual meeting of the Federation of American Societies for Experimental Biology, held at the Lord Baltimore Hotel, Baltimore, Md, March 30 to April 2

Dr Felix J Underwood (Fellow), Jackson, Miss, has been appointed a member of the Rockefeller Foundation Board to serve for a period of three years This Board is composed of six members and decides the policy of the Foundation throughout the world

Recent changes at the University of Colorado School of Medicine, Denver, include the following

Dr Philip Work (Fellow), to Professor of Neurology and head of the department, Dr Constantine F Kemper (Fellow), Associate Professor of Medicine, Dr Harry Gauss (Fellow), Assistant Professor of Medicine

Dr Rollin H Stevens (Fellow), Detroit, was guest of honor at a dinner January 28 given by the staff of Grace Hospital, the Detroit Roentgen Ray and Radium Society and the Detroit Dermatological Society, in observance of his seventieth birthday. Among other gifts Dr Stevens received a leather bound copy of the January issue of "Radiology," which was dedicated to him. Each guest received a reprint of the opening article in the journal, entitled "Rollin Howard Stevens, An Anniversary Chronicle of His Useful Life," by Dr Percy Brown (Fellow), of Boston

Dr George R Minot (Fellow), Boston, delivered a lecture January 20 at the Mayo Clinic, Rochester, Minn, on "Some Aspects of the Etiology, Diagnosis and Treatment of Anemia"

Dr Eugene M Landis (Fellow), Assistant Professor of Medicine, University of Pennsylvania School of Medicine, Philadelphia, delivered the annual N W Jones Lectures at the University of Oregon Medical School, Portland, February 9 to 10. Dr Landis spoke on "Capillary Pressure, Capillary Permeability and the Movement of Fluid Through the Capillary Wall" and "The Effects of Pressor Drugs and Kidney Extracts on Blood Pressure and Peripheral Blood Flow"

The Neuropsychiatric Society of Virginia held its first meeting for 1938 at the University Hospital on January 26. Papers were presented by Dr D C Wilson (Fellow) and Dr Dudley C Smith (Fellow), University, Va

At the February meeting of the New York Polyclinic Medical School and Hospital Clinical Society, Dr Lea A Riely (Fellow and Governor for the State of Oklahoma) spoke on "Modern Concepts of Addisonian or Macrocytic Anemia"

Dr Albert Soiland (Fellow), Los Angeles, has been recently elected National President of the United States Naval Reserve Officers Association. Dr Soiland is a Trustee of the Pan-American Medical Association and attended the 7th Congress Cruise during the course of which he contributed three papers to the program

Dr Joseph H Barach (Fellow), Pittsburgh, Pa, addressed the Allegheny-Garrett County Medical Societies at Cumberland, Maryland, on February 25 1938. His subject was "Science of Nutrition and the Treatment of Diabetes"

Dr Walter A Bastedo (Fellow) addressed the Wayne County Medical Society in Detroit, Mich, on March 7, on "Therapeutics and the Physician's Prescription". He has been the recipient of the "Diploma de Honor" of Venezuela Farmaceutica, which governs the standards of drugs in Venezuela

Dr Erwin E Mayer (Fellow) Baltimore, Maryland, addressed the "Association of Dental Surgeons" on March 23, 1938, on "Oral Infections from the Internist's Viewpoint"

OBITUARIES

DR THOMAS BARNES FUTCHER

Thomas Barnes Futch (Fellow) was born January 1, 1871, in St Thomas, Ontario, Canada, and died February 25, 1938, in Baltimore, Maryland. His early years were spent at home attending the local schools and at the age of 19 he entered the University of Toronto where in 1893 he received the degree of Bachelor of Medicine with high honors. After a year as house officer in the Toronto General Hospital, he went to Johns Hopkins to be a member of the House Staff under his fellow Canadian, Dr William Osler. Seven years were spent in the Hospital, the last three as Resident Physician on the Medical Service. He then entered consultation practice in Baltimore opening an office next door to the home of his beloved chief, Dr Osler. In 1909 he married Gwendolyn Marjory Howard of Toronto who was a daughter of the famous Canadian, Dr Robert Palmer Howard, to whom Dr Osler owed so much of his early medical inspiration.

Dr Futch's career was one of steady progress in the practice and teaching of medicine. At the time of his death, he was Visiting Physician to the Johns Hopkins Hospital where he was Chairman of the Private Ward Medical Service. He was also Associate Professor of Medicine which is one of the highest academic positions open to part-time teachers at the Johns Hopkins Medical School.

He belonged to many medical societies and in 1931-32 was President of the Association of American Physicians. He was made an Associate of the American College of Physicians in 1925 and became a Fellow in 1930. His interest in the local medical societies was always encouraging, he attended the meetings faithfully, and he was Chairman of the Historical Section of the Baltimore City Medical Society in 1937-38. He was one of the original members of the Interurban Clinical Club and rarely missed the meetings of this Club in other cities.

His medical writings were mostly concerned with metabolic subjects although of his many publications more than half were on such various subjects as haemochromatosis, cancer of the pancreas, erythremia, and disturbances of pituitary function. In Osler's System of Medicine he contributed the sections on Diabetes Mellitus, Diabetes Insipidus and Gout.

Dr Futch was a member of a distinguished group of American physicians who continued what Osler began, to balance skillful bed-side observation with the newest laboratory method. He taught, by precept, meticulous care in clinical examination but above all he taught, by example, loyalty to the best medical tradition. His friendship was unfailingly kind—no one can remember his saying anything derogatory about a colleague—and the influence of his quiet, genuinely courteous presence will long be felt.

HENRY M. THOMAS, JR.,
Governor for Maryland

DR MICHAEL ANTHONY BURNS

Michael Anthony Burns (Fellow) was born in Philadelphia on May 23, 1884, the son of James M and Mary A (Rowen) Burns. After his early education in the parochial schools of Philadelphia and at St Joseph's College, he entered the Jefferson Medical College from which institution he graduated in 1907.

On the day Dr Burns began the practice of medicine, following his internship, he entered the neurological service of Dr Francis X Dercum, then Professor of Neurology at the Jefferson Medical College. For thirty years, until the beginning of his final illness, he continued in this department in advancing grades as a teacher and, in 1934, his faithful and skilled services were rewarded by election, after the death of Professor Dercum, to the Professorship of Neurology.

During the World War, Dr Burns was neuropsychiatrist to Base Hospital No 38 (The Jefferson Medical College Hospital Unit) and, after the Armistice, he was appointed consulting Neuropsychiatrist to the District of Paris. Dr Burns, at the time of his death, in addition to his teaching and clinical work at the Jefferson Hospital, was Visiting Neurologist to the Philadelphia General Hospital, Neuropsychiatrist to St Mary's Hospital, Consulting Neurologist to the Wills Eye Hospital, St Joseph's Hospital and the Shriners' Hospital for Crippled Children.

He was a Fellow of the American College of Physicians and the Philadelphia College of Physicians, a member of the American Neurological and Psychiatric Associations and of the Philadelphia Neurological and Psychiatric Societies.

Dr Burns was the author of numerous articles on neuropsychiatric subjects and was a frequent contributor to journals specializing upon such presentations.

On October 11, 1910, Dr Burns married Margaret Agnes Keenan of Philadelphia who, with two sons, Paul V and John A, survive him.

Dr Burns was a popular and appreciated physician and his patients will not find it easy to discover another friend and medical counsellor possessing the same happy combination of pleasing and helpful characteristics. Dr Burns loved life and understood people. In common with all truly successful physicians, he thoroughly enjoyed his professional duties. He worked hard, too hard perhaps, to be able to live long.

Dr Burns' death on March 7, 1938, due to coronary thrombosis, was a grievous loss to his family and numerous devoted friends and to the medical profession of Philadelphia.

E J G BEARDSLEY, M D, F A C P,
Governor for Eastern Pennsylvania

ADMIRAL CARY TRAVERS GRAYSON

Admiral Cary Travers Grayson (Associate) was born at Salubria in Culpepper County, Virginia, in 1878 and died in Washington, D C, on February 15, 1938

He was educated at William and Mary College (1895-1898) and at the University of The South at Sewanee, Tennessee, where he received his M D degree in 1902 He held a degree from the Medical College of Virginia and graduated from the United States Naval Medical School in 1904 He entered the Navy as an Acting Assistant Surgeon in 1903, and was made a Medical Director with the rank of Rear Admiral on August 29, 1916 He was retired from the Navy December 30, 1928 During these years his professional services were eminent and outstanding He served as personal physician to three presidents, William Howard Taft, Theodore Roosevelt and Woodrow Wilson He had a combination of knowledge, insight and sympathy which are the necessary attributes of the good physician His accomplishments from 1928 until the time of his death are a part of our country's history

Admiral Grayson was a member of the Medical Society of the District of Columbia since January 26, 1916, and an Associate of the American College of Physicians from the inception of the College

In the death of Admiral Grayson America lost one of her most distinguished citizens He had devoted most of his life to doing things for other people The sudden shock of his passing has left sorrow among his many friends and admirers the world over During his life he inspired friendships such as are granted to few men Those of us privileged to know him—and the number was legion—can testify to his gallantry and unbounded loyalty His friends and associates found in him a man in whose personal integrity they could always depend and one in whom trust was never misplaced He had a keen analytical mind which inspired many to seek his rare good judgment At the sick bed and in the council chamber his wisdom was particularly manifest and his logical decisions and timely advice were most helpful to his colleagues His kindly disposition and his unfailing sense of humor saved many a trying situation He was a gentleman in every sense of the word and his host of friends have suffered an irreparable loss

In the death of Admiral Cary Travers Grayson, The American College of Physicians has lost one of its most valued and loyal members

The BIO-PHOTOMETER

A standard clinical diagnostic instrument which gives data in relation to the vitamin A status of the subject tested

MODEL C

This model of the Bio-Photometer is used the same as the Standard Model A Bio-Photometer in conducting the test as reported in the Journal of the American Medical Association*. It is designed primarily for use where the Bio-Photometer must be moved about, and taken outside of the building where it is customarily used. It is smaller and more compact, but is complete and ready to operate. It is designed to be used on a table and is provided with an adjusting screw so that it may be tilted at an angle most comfortable for the patient.

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts, Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physicians. The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College.

MANUSCRIPTS All correspondence relating to the publication of papers and all books and monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following style:

4 Doe, J. E. What I know about it, Jr. Am Med Assoc., 1931, xevi, 2006-2008.

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations.

REPRINTS For each article published, there will be furnished gratis fifty reprints without covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are wanted the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and books bearing upon the field of internal medicine. Authors and publishers wishing to submit such material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made in the department of reviews.

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid: \$7.00, United States, Canada, Mexico, Cuba, Canal Zone, Hawaii, Porto Rico, \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. Members of the American College of Physicians receive the ANNALS OF INTERNAL MEDICINE as a part of their membership. Checks should be drawn to the order of W. D. Stroud, M.D., Treasurer, and remitted through the Publication Office or the Executive Secretary's Office.

BUSINESS CORRESPONDENCE All correspondence relating to business matters, advertising, subscriptions to the ANNALS, inquiries concerning membership in the American College of Physicians, et cetera, should be addressed to the Publication Office or to the Executive Secretary. Books and reprints presented to the College Library should be addressed to the Executive Secretary.

KNOX CLINICAL NOTES

ONE OF A SERIES OF CORRESPONDENCE EXCHANGES WITH PHYSICIANS ABOUT KNOX GELATINE

The Glycine Content of KNOX GELATINE

A physician writes, "Pertaining to Glycine—glycocol $\text{NH}_2\text{CH}_2\text{COOH}$ —gelatine contains large amounts of Glycine I feed a great deal of Knox Gelatine to patients suffering from fatigability—'muscle exhaustion'—with very good results in conjunction with the administration of 15 to 30 grams of Glycine given daily. Glycine is rather expensive to patients—about eight dollars per pound. I wish to know the percentage of Glycine in your best grade Knox Gelatine so I may substitute more liberal feedings of Knox Gelatine and cut the pure Glycine dosage down to a lower and more economical level."

The KNOX GELATINE LABORATORY

Replied as Follows:

Thank you, Doctor! You are right about Knox Gelatine. Increasing amounts of it are being fed in asthenic conditions. Knox Gelatine contains 25% of amino acetic acid (Glycine). Goodly amounts can be fed in soups, broths, and other recipes to supply amounts of Glycine in this palatable gelatine form which is so economical. Perhaps the simplest way to feed it is as follows:

Sample and useful Dietary Booklets
on Request Write Dept 476

"THE KNOX MILK STIR"

Place the contents of 4 envelopes of Knox Gelatine in an ordinary drinking glass. Add 4 ounces of cold milk and allow to soak for five minutes. Add 2 more ounces of milk and stir until homogeneous. Then place glass in small cooking kettle of hot water until gelatine milk mixture liquefies. Add 2 more ounces of cold milk, which will bring the temperature to a satisfactory warm drink of about body heat. A tablespoonful of prune juice or a few drops of any bland flavor like vanilla may be added.

Total 8 ounce liquid—about 250 calories

Why you should insist on Knox Sparkling Gelatine

Because Knox Gelatine is 85% protein in an easily digestible form—because it contains absolutely no sugar or other substances to cause gas or fermentation, Knox Gelatine should not be confused with factory-flavored, sugar-laden dessert powders. Knox is 100% pure USP gelatine. Knox Gelatine has been successfully used in the dietary of convalescents, anorexic, tubercular, diabetic, colitic, and aged patients.

KNOX SPARKLING GELATINE
IS PURE GELATINE—NO SUGAR

Clear the way for free breathing in COLDS

The congested nasal mucosa and the hypersecretion in colds can be efficiently brought under control by topical application (dropper, spray, pack or jelly) of the synthetic vasoconstrictor—

NEO-SYNEPHRIN HYDROCHLORIDE

(laevo-alpha-hydroxy-beta methyl-amino-3-hydroxy-ethylbenzene hydrochloride)

The action of Neo-Synephrin occurs promptly after its application, and is of prolonged duration. Additional advantages include

- freedom from sting
- more sustained action than epinephrine or ephedrine
- less toxic in therapeutic dosage than epinephrine or ephedrine
- stability—may be sterilized by boiling
- in dosage recommended, Neo-Synephrin does not usually produce "nervousness" or insomnia

3 Convenient Forms—

Neo-Synephrin Hydrochloride Solution

1/4% and 1% (1-oz bottles)

Neo-Synephrin Hydrochloride Emulsion

1/4% (1-oz bottles)

Neo-Synephrin Hydrochloride Jelly

1/2% (in collapsible tubes with nasal applicator)

» » EXERCISE « «

Exercise is an important factor in the treatment of constipation. Of equal importance are suitable diet and a regular habit time for bowel movement, which under the present mode of living, are often difficult to enforce. For the patient who is unable to exercise or adhere to a suitable diet a regular bowel movement may be brought about and maintained with Petrolagar. It assists in establishing a regular bowel movement because it mixes intimately with the feces to form a soft, easily passed stool. Petrolagar is prepared in five types for choice of medication. Petrolagar Laboratories, Inc., Chicago, Illinois.

*Petrolagar — Liquid petrolatum 65 cc emulsified
with 0.4 Gm agar in a menstruum to make 100 cc*

ALL MAY RESULT IN *Insomnia*

SLEEPLESSNESS as a symptom occurs in a great variety of conditions. To the chronic insomniac, to the restless, nervous or mental case, to the preoperative or postoperative patient, Squibb Ipral Products bring needed rest which may turn the tide in favor of the patient's recovery.

Ipral Calcium or Ipral Sodium are safe, effective sedatives. A small therapeutic dose induces a restful sleep, closely resembling the normal, from which the patient awakens generally calm and refreshed. Ipral is readily absorbed and rapidly eliminated. In the usual therapeutic dose no untoward organic or systemic effects have been reported.

Ipral Calcium (calcium ethylisopropyl-

barbiturate) is supplied in 2-gr. tablets and in powder form for use as a sedative and hypnotic, and in $\frac{3}{4}$ -gr. tablets for use where it is desired to secure a continued mild sedative effect throughout the day.

Ipral Sodium (sodium ethylisopropylbarbiturate) is supplied in 2-gr. capsules for hypnotic use and in 4-gr. tablets for preanesthetic medication.

Elixir Ipral Sodium—This preparation is useful where a change in the form of medication is desirable. One teaspoonful of the elixir represents 1 g. of Ipral Sodium. Available in 16-fl. oz. bottles.

TREATMENT OF BRONCHIAL ASTHMA BY ORAL INHALATION

ADRENALIN CHLORIDE SOLUTION 1:100

THE oral inhalation of Adrenalin Chloride Solution 1 100 is promptly effective in relieving symptoms of bronchial asthma—in most cases results have been quite as satisfactory as those following hypodermic injection of the familiar 1 1000 solution.

Nervousness and tachycardia, as well as other reactions which often accompany parenteral administration, are much less frequent following inhalation therapy. Discomfort and inconvenience of hypodermic injection are obviated by this new treatment

Adrenalin is the Parke-Davis brand of Epinephrine U S P. Adrenalin Chloride Solution 1 100 is accepted by the Council on Pharmacy and Chemistry of the American Medical Association, it is supplied in 5-cc vials, together with dropper for transferring the solution to a suitable atomizer, vaporizer, or nebulizer. The apparatus used must deliver a fine spray entirely free from drops.

NUMBER 11

THE FUNCTION OF THE COLLEGE

By J H MEANS, M D , F A C P , *Boston, Massachusetts*

I SHOULD like to devote the brief time available for a presidential address to a further consideration of certain questions which I put before you at the dinner last year in St Louis, and which are also closely related to some of the problems raised by Dr Miller in his excellent Presidential Address in Detroit, the year before that

The first of these concerns why we call ourselves a College of Physicians Is there any special significance in the fact that we have selected the appellation College rather than that of Society or Association? What, after all, is a college in the sense in which we have used the word and what is its proper function?

We need not trace the evolution of the term from Roman days to our own We may note, however, in passing that for the most part it has, one way or another, usually been connected with affairs of the intellect, with the efforts of man to improve his mind

In America, colleges have been the forerunners of universities In England, the old universities are made up of many colleges These are both social and educational units In Great Britain there are also the professional colleges, the Royal Colleges of Medicine and Surgery

These last, since they are in some measure the prototypes of our own College, are worthy of scrutiny King Henry the VIIIth, in granting a charter to the Royal College of Physicians of London, said "his main reason was to check men who professed physic rather from avarice than in good faith, to the damage of credulous people, accordingly, after the example of other nations, he had determined to found a college of the learned men who practised physic in London, in the hope that ignorant and rash practitioners might be restrained or punished" (*British Med Jr*, April 3, 1915, p 607)

The English Royal Colleges, in addition to other functions, possess those of licensing boards In 1913, Mr R J Godlee, addressing the American

* Presidential address, delivered at the Convocation of the American College of Physicians, Twenty-Second Annual Session, New York, April 7, 1938

College of Surgeons, at its foundation, on the "Origin and Growth of the Royal College of Surgeons of England" (*Lancet*, 2, 1913, p 1443), remarked that "If you desire that the diploma" F A C S "shall indicate, not only that a man can pass a severe examination, but that he has been thoroughly well trained, you will be well advised to lay down a special curriculum (I speak the word with dread) over and above that required in the ordinary university course, and to frame the examinations on a standard even higher than the highest degree examinations. It is, in my opinion, essential that the examination should be conducted independently of any medical school, and that the examiners should be chosen only from those who are actually engaged in teaching. It is also highly advisable that examiners should, whenever it is possible, be Fellows of your College and that no candidate should be examined by his own teacher."

Neither the American College of Surgeons nor the American College of Physicians can attain to this quasigovernmental status of the British Royal Colleges. They have no charters, royal or otherwise. They are self-appointed and possess constitutions drawn by their founders in place of charters. None the less, through the prestige which they are gaining, they may accomplish in the elevation of professional skill and learning, something akin to what the Royal Colleges accomplish through authority.

It is probably for the best in this country that minimum standards of professional qualifications be set and enforced by the state. It is for the profession voluntarily, through its various institutions, and by the efforts of its individual members, ever to strive far to exceed these minimum requirements. This is in accordance with sound American tradition. The various boards for certification in specialties, like that for internal medicine which is fostered by this College in collaboration with the American Medical Association, are examples of voluntary efforts for improvement in the quality of professional work.

The College, however, must be more than an instrument for raising standards of practice, if it is to deserve the name of College. To be worthy of such a name in truth it must become a breeding place of ideas, a nourisher of learning, a defender of intellectual freedom, a builder of professional morals, a forum in which can be expressed *any* honest opinion relating to the practice of physic in *any* of its aspects, with the assurance that such opinion will receive dispassionate and disinterested attention and study, and that it will be appraised judgmatically in the light of experience. Should the College be merely another medical society, then it is in fact, not a college at all in the highest meaning of the term.

Let us consider for a moment our national medical association and the relation of this College to it. "Organized medicine," the Association has called itself, "the doctors' trust," it has been called by members of the laity, an institution, be it said at once, which has accomplished great good, but one which by reason of its political nature is subject to certain limitations by which, on the contrary, a College such as this one of ours, is not bound. I

apply the term political to the American Medical Association advisedly I use it descriptively, not critically Its organization is patterned somewhat after the political structure of the United States Its relation to state societies is roughly analogous to that of the federal government to the states themselves The behavior of the Association is political It is partisan behavior, it champions a cause At the present time the cause is something close to standpatism But the policy can be changed at any time, if the membership wills it, just as can that of the federal government, if the citizenry wills it At the present time the electorate of the American Medical Association is apathetic and marticulate because it has no issues, no platforms set up to vote for It is allowing the medical politicians to run things about as they please, and official spokesmen, like Jove on high Olympus, to hurl their thunderbolts of wrath at all who differ with orthodox doctrine As no democracy can be healthy without freedom of speech, real issues and an effective opposition party, it is desirable that those who believe in popular government bestir themselves to change this state of affairs The British recognize this need so thoroughly that in Parliament, I am told, they speak of His Majesty's Loyal Opposition .

It is not my intention to devote this address to a critique of the American Medical Association I have said what I have said in order to indicate what I conceive to be the fundamental difference between a college of physicians and a national or state medical society Each has its use, but they are different The college is not in competition with the medical association The college should be the counterpart of the university, not that of the state It is only through general elevation of the cultural level of society that a democracy can rise above mediocrity The germinative centers of culture are the universities This has been so since antiquity They are the noblest institutions of man They stand for no ulterior purpose They are free as no other institutions are free They are committed to no fixed policies other than that of acquiring and disseminating wisdom It should be as unthinkable for us to have a College policy regarding social, economic, political or scientific aspects of medicine as for one of our universities to take sides in a political campaign It should also be unthinkable that we should at any time be unwilling to hear all sides of any problem related to the practice of medicine

We are in great need, as was made clear by Dr Miller in Detroit, of medical statesmen, men of intellectual honesty, breadth of vision, courage, nobility of purpose and the qualities of leadership, who can find the way to the solution of some of the problems of medical service which now baffle both the profession and the public The development of enlightened opposition within the democracy of the national association is one way of bringing to light such leaders, the development of a university atmosphere in a College such as this, is another

The behavior of the College must be that of scholars The College must not seek through propaganda to reach veiled objectives, but rather it must

search for, and broadcast, the whole truth, insofar as it can ascertain it, in all matters relating to the work of the physician. It must set for the profession at large an example of fine professional character. These are its proper functions. It is as desirable that its membership include men of thoroughly diverse opinion as it is that university faculties should do so. We want no society of "yes-men," we want genuine thinkers, and if we have genuine thinkers, we are bound to have diversity of opinion, because, as a speaker, I recently heard, remarked, "the only persons who think alike are those who do not think at all." In this connection, I should like to quote an editorial which appeared in 1933 in the *Lancet* (October 7, 1933, p 812) "From the moment that the idea of any tests or qualifications for university teachers other than those of ability and intellectual honesty is entertained, decay must begin. 'Cleverness, talent, skill, fluency, memory, all these are understood and rated in the market. A cultivated mind just because it is above all price is apt to be overlooked altogether.'" There is an idea here which this College may profitably make use of in selecting its members.

May I return to the American Board of Internal Medicine. This examining body which is the offspring of the College and of the American Medical Association requires that for certification as internists candidates must possess certain qualifications and must have had certain training.

The question arises at once then. Where are they to get this required training? Our sister College, the American College of Surgeons, has concerned itself with this question. Recognizing the internships and residencies of the United States, in a host of hospitals, taken collectively, as one great educational institution, it fancies itself, so far as the training of surgeons goes, as the coordinating, directing and administrative center. To use the somewhat imaginative language of the Chairman of its Board of Regents, the hospitals of the country, which train residents in surgery, are part of the campus of the American College of Surgeons. This may be subjecting the term campus to considerable strain, but none the less the idea is made clear by this wording. The College of Surgeons visualizes itself as constituting, in cooperation with the hospitals, a great college for graduate training in surgery, a training which will make it possible for men to qualify for certification as surgeons by the Board of Surgery. The College of Surgeons, furthermore, has invited the College of Physicians to cooperate with it and to perform in medicine a similar function. To what extent or in what way it is wise for us to do so has not been determined. It is a problem in which the part of wisdom is to proceed carefully. Certainly it is true that whereas the universities of the country have provided well for undergraduate teaching and for medical research, for graduate teaching they have done relatively little. Under these circumstances, there is an opportunity for the Colleges, that of Physicians as well as that of Surgeons, cooperating possibly with hospitals—far better I think with medical schools—to arrange for the continuation of professional training to the highest levels attainable.

The requirements for membership in the College are related to these matters. When the American Board of Internal Medicine successfully establishes itself as the generally accepted agency for certifying internists, then it will be logical for this College to make certification by it, or by an equivalent board in one of the other medical specialties, a prerequisite of membership.

Some of you may recall that at the Boston meeting in 1929, Dr. George Vincent told us we were an elite—a self appointed one at that. He said further that everyone wishes to become a member of an élite. If he cannot get into an existing one, he starts a new one, and after he has got all his friends in, he raises the entrance requirements. He intimated that that is what we have done. The jest is not devoid of application, but this need not depress us. So long as we do it for a high purpose, it is neither dishonest nor hypocritical for us steadily to raise our entrance requirements, even to a point where some of those of us already in could not pass were we to seek to enter now. The significance and usefulness of the College in the intellectual world of our profession will be determined entirely by the mental calibre, the moral fibre and the learning of its members. Anything we can do to elevate these is justifiable, anything we can do to promote the growth of medical scholarship is meritorious. The physician must continue to study throughout his life. The College must be made an instrument to help him do so.

Let us consider for a few moments what may be a proper scope for the deliberations and discussions of the College at its Annual Sessions, its regional meetings, through the medium of its journal, and the informal intercourse among its members. We were told in St. Louis that the doctor should stick to his last, a metaphor intended to mean apparently that we shouldn't bother our heads about anything but the scientific aspects of medicine. The social, economic, political, and even the philosophic aspects are none of our business. I hardly think it is necessary to seek arguments to refute this pronunciamiento. It is palpably as ill balanced as is its opposite which we sometimes hear, that no one but the doctor should have any say in the regulation or method of dispensing medical practice.

The social, economic and political aspects of medicine certainly may rightfully engage the attention of a College of Physicians. That is why I have included, cautiously, a few such items in the present program. They also are of immediate concern to the public, the individual members of which—Johnnie Q., for example—may at any time become patients. Recently they have aroused the interest of both profession and laity to an unusual degree. They have given rise to a considerable amount of somewhat acrimonious discussion. That this should be so is altogether gratifying, for such discussions sometimes clear the atmosphere and thus permit a clearer view. Also there is the possibility that from them will emerge an idea or two, actually constructive.

I will not dwell longer on the social, economic or political aspects of

medicine. Instead, I should like to suggest briefly certain types of philosophical, or at least ethical, problems which I think might advantageously be included from time to time among the topics to be deliberated upon by the College. For example, the question of whose medicine is it? or does the patient exist for the doctor, or the doctor for the patient? The answer to this would seem simple, that the doctor exists for the patient, and yet when we get involved in problems of the provision of medical care, the conditions of medical practice, the methods of paying the doctor, the ethics get very complicated. The practice of medicine—is it a business or a profession? A profession, of course, you'll say, but what's the difference? The motive of business is profit. What is the motive of a profession? Profit also, but not profit alone. The professional man expects, and ought, to earn his living by practicing his profession. The physician wants, and is entitled to, adequate remuneration, but in addition he gets a part of his reward from the intellectual enjoyment which a calling requiring some learning bestows upon him (this reaches its highest pitch when he is able to make an original contribution to medical knowledge) and from the spiritual values which are to be derived from associating in a helpful way with many kinds of people. The profit element and the pleasure element both enter into the motivation of the physician. In considering his behavior and his relations to other classes in the community, it is best to face these facts realistically. It is idle to think of the physician as a consecrated sort of person giving himself idealistically to the cause of suffering humanity. Rarely he may be just that, as occasionally there are saints in other lines of human endeavor, but the rank and file of him are not, nor is it altogether desirable that they should be. If the laity wishes to idealize us, let it do so, but let us not be led from the truth of the situation thereby. As a matter of fact, the laity is more inclined nowadays to damn the doctor than to idealize him, and this is largely due to his inability to make his methods of dispensing medical service as efficient as a streamlined age requires. The layman, who may become a patient, is just as personally interested in the manner of provision of medical care as is the doctor, and I believe that any disinterested judge would say he had as good a right to be. The practice of medicine is the doctor's to make an honorable living by, and ideally to gain some happiness by, it is the layman's to have his health preserved by, the patient's to have his ills relieved by. When the interests of doctors and patients come into conflict, compromises must be reached through the display of fairmindedness on both sides.

We hear a great deal about the sacrosanct doctor-patient relationship. No third party can be allowed to come between the two involved. This has been used as an argument against all attempts to improve the efficiency of medical service through group practice. When it is suggested that a disinterested outside person could with greater equity than the doctor determine what might be a proper fee for services rendered in any given case, there are storms of protest from the conservative wing of the profession.

Yet a philosopher might recognize such an arrangement as an ideal one, and, as a matter of fact, it is actually working successfully in more than one place to the satisfaction of both doctors and patients. Professor Lawrence J. Henderson has considered the doctor and patient as a social system, analogous somewhat to a physico-chemical system, two elements acting upon one another through sentiments. The doctor must seek to influence the patient through the patient's sentiments, and he must take care not to let the patient's sentiments act upon him. In other words, he must keep his own sentiments out of the picture as much as possible. He must perform his professional duty disinterestedly, but if he is wondering all the time what sized fee the patient can pay him, or what sized fee it is fair for him to ask of the patient, how can he remain disinterested? I submit that having a third party determine the size of, and even collect the fee from the patient for the doctor, is not only not an intrusion into the holy doctor-patient relationship, but actually increases the likelihood of the patient's receiving from the doctor the best and wisest treatment the doctor is capable of giving.

Another thing that stimulates the doctor to do his best by his patient is to have his work overseen by his critical colleagues. If this is an intrusion into the holy relationship, then it is to the patient's best interest to have an intrusion. I do not believe that it can be successfully denied that the place where a patient is most likely to have his case diagnosed and treated correctly is in the public wards of a teaching clinic. This is not because the doctors are necessarily any wiser there, but because if one makes a mistake, another will observe and correct it. If one has some new information about diagnosis or treatment that applies to a given case, he will tell his colleagues about it. Why in former times did patients walk from Jerusalem to the Allgemeines Krankenhaus in Vienna? Because they knew that in that center of medical learning they stood the best chance of getting cured.

One other ethical question I should like to indicate. Is it noble or ignoble, is it wise or otherwise, that physicians and surgeons should give their professional services to the care of the indigent? There is also an economic question connected with this matter, but it is quite simple, namely, if doctors are to be paid for caring for the indigent, who is going to pay them? The answer to this is quite obvious. If they are to be paid at all it will have to be by the community because there is no other source. The ethical problem is more puzzling. By tradition, down through the ages, the physician has given his services to the poor. The fact that this has always been so, however, does not of necessity prove either the wisdom or the justice of the custom. Should the physician give his service to the indigent? Is he more obligated to see that the indigent get adequate care than is any other responsible member of the community? He possesses the skill to get them well perhaps, but should he be expected to give this away when other members of the community are making no parallel sacrifice? Of course, other members of the community will readily accept his gift so long as he is willing to make it. But why does he make it? Because it is traditional for him to

make it. Also because he gets a return for it, not in money, but in experience, in the prestige that attaches to a good hospital appointment (the indigent are cared for largely in hospitals), in the pleasure that is to be derived from associating with the other members of the staff of such an institution and, finally, in the spiritual uplift that is to be got from giving of one's self to the service of others.

Whether these rewards are adequate is a fit subject for discussion. Under ideal circumstances, as, for example, in privately endowed teaching clinics, undoubtedly they are. In large publicly supported hospitals, where the pressure of work is great and much of it is of a drudgery type, perhaps they are not. It must be admitted that if the profession should abandon its traditional custom of giving its service freely to the poor, something of an intangible or spiritual nature would be lost. However, we have to face the realities of our own day, and it is not unlikely that in many instances at least the indigent will get better medical service if the community pays for it.

It may be proper to add that even if the doctor is paid for caring for the indigent, he still has the opportunity to exercise his generosity, as does any other citizen, by giving of his substance to the most that he is able to the worthy causes of his community. Let him show the world that the doctor can be as good a citizen as any. Let him also, in rendering the service for which he is paid, add to it those qualities of spirit and purpose which cannot be bought with gold. Therein lies his chance to preserve the ancient values in the face of modern adaptations.

I must now draw this utterance to a close. I have sought to indicate to you my conception of a College of Physicians, of its nature and purpose, of its attitudes and of the scope of its deliberations and activities. In conclusion let me urge all members of the College, especially new members, to put, as members, scholarship first. Let me remind you that scholarship flourishes only in the atmosphere of freedom. There is indeed no place for "yes-men" in a truly learned society, nor is there place for political maneuvering, or reprisal for the expression of honest opinion. Recall the words of Voltaire, "Ecrassez l'infame." The infamy of which Voltaire spoke was religious bigotry. The bigotry of which we stand in dire peril today, as President Conant pointed out at the Harvard Tercentenary, is political bigotry. Let us strive, therefore, in this propaganda-poisoned world, to keep our land a free democracy and within it to make our College take on the essence and spirit of the university and thus become an instrument of service to humanity.

NEW EXPERIMENTAL DATA ON ARTIFICIAL HYPERTHERMIA

By A BESSEMANS, M D , Ghent, Belgium

GIOVANNI Truffi recently reported that *Treponema pallidum* remains virulent when passed for one hour through the body of birds, which are supposed to have a body temperature of 42° C (107.6° F) Mario Truffi and Beck theorized on these results, and reached the bizarre conclusion that *Treponema pallidum* could resist, within the organism of birds, temperatures of 42° C (107.6° F) during at least five hours They deduced from the experiments of Giovanni Truffi that mere thermic rise is not the cause of the action of malaria therapy and of pyretotherapy in general

FIG 1 Examples of superficial and deep tissue temperatures in birds (2 chickens, 1 rooster and 1 pigeon)

We believe that we have disproved these assumptions We have repeated the experiments of Giovanni Truffi, and have accurately measured, by means of thermocouples, the temperatures of various parts of the animal body during experiments involving ten hens, three roosters and eight pigeons In the first place, as is shown by the accompanying graph (figure 1), the temperatures of various parts of the bodies of these animals vary

* Presented at the St Louis meeting of the American College of Physicians, April 21, 1937

From the Institute of Hygiene and Bacteriology of the State University of Ghent, Belgium

tremendously, notably from 35° C to more than 42° C (95° F to 107.6° F). Hence, if treponemas lodge in cool parts, they may retain their virulence. Secondly, we believe that the experiments of Giovanni Truffi must have been carried out under peculiar conditions, because we were not able to confirm his results.

The blood, as well as emulsions of the liver, spleen, brain, spinal cord, and several lymph nodes of our 21 experimentally infected birds, failed to produce a single syphilitic lesion, when injected into the testicles of 42 rabbits which survived for at least four months. The popliteal lymph glands of these rabbits also remained sterile.

Furthermore, we must call attention to the fact that, as a syphilitic strain is passed through a series of rabbits, it gradually becomes more virulent for this animal. It is not far afield to assume that this is connected with an increased resistance of the strain to temperature. Giovanni Truffi worked with a strain which had serially passed through the bodies of hundreds of rabbits, since it was isolated about 30 years ago. As our own strains have aged, they have become more virulent. In some cases also, they seemingly have become more thermo-resistant. In 1928 we were able to prevent the appearance, or to cure syphilomata of rabbits in 7 out of 13 experiments, by transposing the testicles for several hours into the abdominal cavity (table 1). In 1935 (same table), this was possible in only three out of 22 experiments.

We have shown that there is a considerable variation of the temperature of different parts of the body of normal birds. Tables 2 and 3 show that this variation also exists in the organs and tissues of normal rabbits. It should be noted (table 3) that there is a variation of more than two and a half degrees centigrade (5.5 degrees Fahrenheit) in the temperatures of such a small organ as the eye of this animal. Even when hot baths are given to a rabbit (table 4), there is a variation of temperature in the various parts of the body.

Table 5 shows that the position of the active and of the inactive electrode, during local diathermy of the deep organs of the true pelvis, has a decided influence on the temperature obtained in the cervix (6 to 14 measurements were made on each of 12 women, to obtain the averages recorded in the last column).

Analogous variations with the mode of application were observed, during local diathermy, in different parts of the abdominal cavity of the rabbit. This was accomplished by means of accurately calibrated thermocouples, inserted through the anal opening, as is shown by the roentgen-rays (figures 2 and 3).

When temperatures are measured in the electrical or electromagnetic high frequency fields, the latter must be discarded if resistance pyrometers or thermocouples are used. Mercury thermometers are only reliable, within the fields, when inserted into the tissue. On the contrary, quartz and even

ultra-short wave apparatuses, or surrounded by the coil of an "inductotherm," they do not record a fall of the temperature directly after the current has been turned off Figures 4, 5 and 6 show syphilitic rabbits being treated by a "diathermax" apparatus (medium waves), an "inductotherm" (short

waves) and an "ultrapandoros" (ultrashort waves), the temperature of a syphiloma or a popliteal lymph gland, of the neighboring air, of the mouth and the rectum being measured, in the course of the experiments, with the

FIG 3 Same roentgen-ray as in figure 2, the tube having been pushed farther the end bends towards the left iliac fossa

benzene or mineral oil thermometers, without it being necessary to turn off the current

In these cases, there is a great variation of the temperature of the measured infected regions (syphilomas and popliteal lymph glands), as long as they are not covered. On the contrary, if in similar experiments these

FIG 4 Comparative thermic measurements of a left testicular syphiloma in the rabbit, of the neighboring air and of the rectum, in the course of a treatment by a "diathermax" apparatus (electric short wave diathermy of 18 meters) applied bipolarly the special Zondek thermometer was placed within the syphiloma

FIG 5 Comparative thermic measurements of a left popliteal lymph gland in the rabbit, of the neighboring air and of the rectum, in the course of a treatment by an "inductotherm" (magnetic short wave diathermy of 25 meters), the cable forming a solenoid around the body, the special Zondek thermometer was placed within the tissue at the level of the gland

regions are insulated against heat-loss by covering them with cotton, high local temperatures can regularly be obtained

Some animals die of heat stroke during such experiments. But if the temperature of a testicular syphiloma is raised to 42°C (107.6°F) for one hour by this method, a destruction of the syphilitic germ in the organ usually results, this is frequently not the case when a same temperature is produced in a popliteal lymph gland

Thus, in our experience, the increased thermo-resistance "in vivo" of the treponemas of the superficial lymphatic system of the rabbit also exists against short and ultrashort wave radiation. Besides, neither the wave length nor the physical modality used has any effect *per se* on killing the

FIG 6 Comparative thermic measurements of a left testicular syphiloma in the rabbit, of the neighboring air, the rectum and the mouth, in the course of a treatment by an "ultrapandoros" (electric ultrashort wave diathermy of 4 meters), applied monopolarly the special Zondek thermometer was placed within the syphiloma

treponemas, the important factor is the height of the temperature of the lesion

It is well known that if a rabbit with a testicular syphiloma is immersed in a hot bath, the syphiloma disappears under definite conditions of temperature and time. If the entire animal develops a sufficiently high fever as a result of the hot bath and if the infected testicle does not come in contact with the water, its syphiloma heals or not, according to whether it is surgically fixed within the abdominal cavity, or is in a position where it is kept cool. This disproves the rather absurd claim advanced many years ago, that water has anything to do with healing syphilis. It proves that the favorable healing effects are caused by heat,

We have also demonstrated that in man, whatever are the physical heating procedures used, neither the mobility nor the virulence of the treponemas nor the clinical aspect of the syphilitic lesions is affected, if the local temperature is not high enough. The exposure of a lesion to an intense electric field does not produce any changes, even if the intensity is so strong as to burn the superficial tissues.

Finally, we have experimented "in vitro" with an emulsion of an Ehrlich sarcoma of the mouse, with various bacterial cultures, and with an emulsion of guinea pig blood rich in trypanosomes. If any of these products are exposed to the action of short or ultrashort waves, a sterilization can be obtained. If, however, the test tubes containing the products are cooled at the same time by means of air or flowing water, this is not true, if the temperatures of the emulsions and cultures are kept low enough to prevent the thermic action of the electric waves. Therefore, it is apparent that, in these experiments also, we are not dealing with any specific wave effect. As an example, table 6 proves this fact for *Trypanosoma gambiense*, treated by short magnetic waves.

There are some paradoxical facts which we have recently observed when heating testicular syphilomas of rabbits by means of certain medium diathermic currents. It sometimes happens that, even if local temperatures which should be adequate for healing the lesion are applied, no healing effect is obtained. It also happens occasionally in this treatment that if a lesion is cooled by air-blowers to such an extent that no healing should result, the treponemas nevertheless disappear, and the lesion heals after a few days.

TABLE VI

Influence of Short Magnetic Waves of 25 Meters ("Inductotherm") on an Emulsion of Guinea-Pig Blood Very Rich in Trypanosomes (Arsenoresistant Strain of *Trypanosoma gambiense*)

| Duration of irradiation (in minutes) | Temperature (in °C) of emulsions | Density in mobile Trypanosomes | Aspect of parasites |

* Inoculation in the guinea-pig negative

† Inoculation in the guinea-pig positive and persistence of arsenoresistance

These paradoxical reactions may possibly be explained by a change in thermo-resistance of the germ, by some effect of high frequency currents on the neuro-vegetative system of the rabbit, or by other as yet unknown factors. The reaction of the whole organism becomes evident in these cases. At present such observations are confined to the rabbit.

Following the ideas of Walter M. Simpson and Clarence A. Neymann that a judicious combination of chemotherapy and pyretotherapy might accomplish more than if either therapy is used alone, we devised a method by which rabbits could be treated with artificial fever and appropriate chemical substances. A cabinet was constructed of wood, without the use of nails or metal parts. The animal was heated in this cabinet by hot air alone (figure 7) or by hot air combined with electromagnetic induction (figure 8).

FIG 7 Special heating cabinet for general aero-pyrexia in the rabbit

FIG 8 The same cabinet as in figure 7, with the cable of an "inductotherm" wound around it, for general aero-inductopyrexia in the rabbit

If an alone was used for heating, we began with a temperature of 55° C (131° F), and continued at about this level until the rectal temperature reaches 41.5° C (106.7° F), at this point the temperature of the air of the cabinet is reduced to 42° C (107.6° F)

By careful technical manipulation of the an temperature and the intensity of the magnetic field, the rabbits' fever may be maintained at approximately 42° C (107.6° F) for one-half hour. The rabbit is more sensitive to artificial fever than man, probably because of its deficiency in perspiration. It was, therefore, impossible to maintain the temperature for as long a period as has been possible in man.

Nevertheless, an average temperature of more than 42° C (107.6° F) was reached in 11 rabbits which survived. Six of these animals were treated with artificial fever alone, while five were treated with artificial fever combined with arsphenamine. For purposes of comparison, 5 rabbits were treated with the same doses of the drug without fever.

The results appear in table 7. The lymph gland transfer into the testicles of a new series of rabbits was positive in 2 of the 5 animals treated only with arsphenamine. Two of the 6 rabbits treated with fever alone also gave positive transfers. As yet we have not been able to secure positive transfers from any of the 5 rabbits treated with fever and arsphenamine.

TABLE VII
Physiothermo- and Chemotherapy, Single or Combined, of Rabbits Recently Cured of Testicular Syphilomas

| Rabbits | Age of syphilis at the beginning of treatment | General hyperthermia | | | | Number of injections of 0.25 cc of solusal varsan per Kg | Lymph gland transfer | |

(*) P = Positive N = negative

We realize that these results are inconclusive. First of all, not enough experimental data are available. Secondly, not enough time has elapsed, either between the end of the treatment and some of the transfers, or since the transfers were made. Thirdly, negative results of lymph gland transfers, even when made in optimum conditions, are not absolutely conclusive. We are now working with a larger series. We believe, however, that the results achieved thus far are suggestive.

We have not employed serological tests for our rabbits because, as has been shown in our previous publications, rabbits, when infected only with the pallidoid treponema (*Spinochaeta cuniculi*), may give positive serological tests. Syphilitic rabbits may give negative tests. Normal rabbits may even give positive tests. Serological tests are, therefore, valueless in this species.

CONCLUSIONS

1 The ideas advanced by Giovanni Tuffi that the *Treponema pallidum* remains virulent after passage for one hour through the bodies of birds have been disproved.

2 The position of the active and of the inactive electrode during local diathermy of the abdominal organs, in the rabbit and in man, has a decided effect on the deep temperatures reached.

3 Quartz or glass thermometers filled with benzene or mineral oil can be employed for the measurement of temperatures in high frequency fields. Such thermometers are not affected by electromagnetic waves.

4 There is a difference "in vivo" in the thermo-resistance of the *Treponema pallidum* of the external syphilitic lesions of rabbits and man, compared with the treponemas found in the lymph glands of syphilitic rabbits. In the latter case the thermo-resistance is so great that it surpasses that of the organism of the host.

5 Neither the wave length nor the physical modality used has any effect *per se* on killing the *Treponema pallidum* within the tissues. The important factor is the height and duration of the temperature of the lesion. The healing effect must be considered in the light of the temperature variations which exist in various parts of the animal body.

6 Paradoxical and unexplained results after treatment with diathermy occasionally occur in rabbits. This is a sign of the reaction of the animal organism as a whole.

7 If bacterial cultures, treated "in vitro" with intense short or ultra-short wave radiation, are cooled so that no heating effect results, they are not affected. The same fact applies to emulsions of an Ehrlich sarcoma of the mouse, and to trypanosomes.

8 A judicious use of the combination of chemotherapy and pyretotherapy seems to be more effective in the syphilitic rabbit than when either therapy is used alone. Serological tests for syphilis are valueless criteria in judging the presence, the progress or the persistence of the disease in rabbits.

DRUGS IN THE TREATMENT OF HEART DISEASE *

By ROBERT L. LEVY, M.D., F.A.C.P., *New York, N. Y.*

"THE following remarks consist partly of matter of fact, and partly of opinion. The former will be permanent, the latter must vary with the detection of error, or the improvement of knowledge. I hazard them with diffidence, and hope they will be examined with candour, not by a contrast with other opinions, but by an attentive comparison with the phenomena of disease." With this paragraph, William Withering, in his *Account of the Foxglove*, published in 1785, opens the chapter dealing with "Practical Remarks on Dropsy, and Some Other Diseases" ³⁶. Certainly, there could be no more appropriate comment with which to begin this discussion.

In any therapeutic program, the use of drugs is but one form of procedure. In the treatment of cardiac disorders, medicinal remedies play an important part because in many conditions they are strikingly effective, often their proper use is responsible for the saving of life. They serve three main purposes: (1) to cope with acute upsets, (2) to restore the function of a failing heart and to maintain it at the optimum level of competency, (3) to prevent the occurrence of disturbances in the circulation, or their recurrence once they have appeared and been adjusted. Numerous remedies have been proposed and tried. Some have stood the test of clinical usage, others, though of proved value, have been supplanted by better drugs which newer studies have made available, many have been found wanting and have been discarded.

It would be neither feasible nor profitable to attempt, at this time, a consideration of all medicinal substances which are known to have an action on the circulation. A few of the more important have been selected which, in the light of current concepts, are regarded as exerting a beneficial action. In its presentation, the material has been divided according to various clinical conditions which can be aided by drug therapy rather than, primarily, into groups of drugs. Although, in some instances, this method calls for repetition, it seems of more practical value, for even though the same remedy may be discussed more than once, the indications for its employment often vary, as well as the manner in which it is best given.

MYOCARDIAL INSUFFICIENCY

Digitalis ²⁴ When symptoms and signs indicate that the heart has failed to function adequately as a pumping mechanism, the administration of digitalis is indicated. This statement holds true, regardless of the

* Read before the Cleveland Academy of Medicine, Cleveland, Ohio, December 17, 1937.

From the Department of Medicine, College of Physicians and Surgeons, Columbia University, and the Medical Clinic of the Presbyterian Hospital, New York City.

etiological type of cardiac disease, nor does it matter whether failure is predominantly of the left or the right ventricle. Many of the older clinicians believed that the foxglove was effective only when the auricles were fibrillating, but accumulated experience has proved that an equally beneficial result is obtained in the presence of regular, sinus rhythm.

The mode of action of digitalis on the heart has been the subject of much study. It exerts its influence in part through a direct effect on the cardiac muscle, and in part by stimulation of the vagus nerves. The myocardium reacts by an increase in the amplitude of ventricular contractions. In the normal person, the size of the heart becomes smaller and cardiac output is decreased. In patients with congestive failure digitalis also brings about diminution in cardiac size, but when the heart is dilated, shortening of the muscle fibers is accompanied by increased cardiac output and hence, improvement in the state of both pulmonary and systemic circulations.^{29 31}

The effect on the auriculoventricular conduction system, which, in cases of auricular fibrillation is responsible for slowing of ventricular rate and, in those with normal rhythm, may cause varying degrees of heart block, is due to a double action. There is depression of the junctional tissues and vagal stimulation. Both of these effects can be demonstrated by observing the response to atropine after giving digitalis to patients with auricular fibrillation. There is partial release of the vagus, with increased ventricular rate, but the level of tachycardia is not as high as before digitalis was given, and the effect on the T-wave of the electrocardiogram persists.

When regular rhythm prevails, the heart rate is not slowed by a direct action. One of the compensatory mechanisms for maintaining the circulation when the heart has failed, is acceleration of rate. When ventricular discharge is increased, there is no longer need for this reflex mechanism to operate, with adjustment of the circulation, the heart beats more slowly. Nor is any specific change induced upon either systolic or diastolic blood pressure, such alterations as may occur are due to modifications in general circulatory dynamics. Hypertension, therefore, is not a contraindication to the use of digitalis, frequently, with the relief of heart failure, the level of the pressure becomes lower.

The diuresis which occurs after digitalis administration is not due to stimulation of the renal epithelium. It is the result of improvement in the general circulation. Venous stasis in the kidneys is relieved and an adequate flow of blood through them is resumed. This point must be kept in mind in relation to the use of diuretics.

The choice of a preparation is of some importance. The chemistry of the digitalis bodies is still imperfectly understood. Various glucosides have been isolated and numerous so-called "purified" substances are on sale. There is no better form of digitalis for oral use than the whole leaf, dispensed as tablet, pill or capsule. The tincture, even though active, has an unpleasant taste and necessitates careful measurement of each dose. The discrepancy between the volume of the drop and the minim makes for con-

fusion and uncertainty. The infusion, because of its instability, has been generally discarded. For intramuscular or hypodermic injection, liquid preparations are marketed in ampules, which should be of hard glass to prevent deterioration. Soft glass yields alkali which, in time, renders the contents inert.²¹ On those rare occasions when intravenous injection seems imperative, crystalline strophanthin is the drug of choice.

Biological standardization of digitalis products, necessary because an accurate method of chemical assay is not available, has become the usual practice with manufacturers. Although the one-hour frog method is still recommended in the U. S. Pharmacopoeia, some modification of the intravenous cat method, introduced by Hatcher and Brody in 1910, has come into widespread usage and is generally favored. Approximately 0.1 gm ($1\frac{1}{2}$ gr) of powdered leaf, 15 minims (1 cc) of tincture and 0.1 mg ($\frac{1}{60}$ gr) of strophanthin are equivalent to 1 cat unit, as commonly prepared. Dosage is expressed in terms of cat units. Assay on animals is far from ideal. The results are not always transferable to man because of variability in absorption and because biological activity and therapeutic potency do not always parallel each other. It is the best method now known and has served to do away with the gross variations in strength which, twenty-five years ago, made even approximate dosage entirely a matter of trial and error.

When possible, it is best to give digitalis by mouth. The oral route is simple, safe and efficacious. If the dose is adequate, a beginning effect on the heart can be obtained in from two to five hours, a maximal effect in from six to twelve hours. In the presence of nausea or vomiting, or after surgical operation, digitalis may be administered by rectum, as the tincture, or in a suppository.¹⁹ Absorption is good and the speed of action is comparable to that observed when similar doses are given by mouth. Intramuscular injections may be made when the oral and rectal routes are not available. Intravenous injection is always attended with some hazard. A high level of concentration is quickly attained and the margin between therapeutic and toxic dose is relatively small. Intravenous injection should never be made if the patient has received digitalis within the preceding week, because of the danger of cumulative effect. Introduction of a digitalis body directly into the circulation is rarely necessary and should be done only in emergencies. As a rule, if the need seems immediate, digitalis will not avail.

The optimal total therapeutic dose varies according to the degree of cardiac insufficiency and the susceptibility of the individual. In general, the more advanced the failure, the greater is the amount required. The total dosage for inducing full effect in a person who has not previously received digitalis within two weeks is between 1.0 and 2.0 gm (15 and 30 gr). It is usually safe to administer 1.0 gm in divided doses during the first 24 hours, these may conveniently be given at intervals of four or six hours. In the second 24 hours, 0.5 gm may be given in divided amounts at similar intervals. Subsequent therapy depends upon the effects obtained and those

regarded as desirable. If haste is not necessary, smaller amounts may be given over a longer period. Relatively large doses are tolerated by children.

After the restoration of compensation, it is often of advantage to continue each day the administration of small maintenance doses over a period of weeks, months or years. This is almost invariably necessary in patients with permanent auricular fibrillation, in order to keep the ventricular rate at a properly low level. The optimum rate must be determined in each case but is usually between 70 and 80 per minute, at rest. A daily ration is useful also in older persons with enlarged hearts, in them a continued "tonic" effect may prevent the recurrence of failure, particularly if the amount of cardiac reserve is small. Digitalis disappears from the body, either by elimination or destruction, at the rate of approximately 0.1 to 0.2 gm (1½ to 3 gr) in 24 hours. But as little as 0.05 gm or as much as 0.3 gm daily may, on occasion, be the dose required for holding a continued effect at the desired level. Each patient, in this respect, is the subject of experiment.

Calculation of dose according to body weight is not necessary. It affords to the physician a false sense of accuracy based on a formula which is subject to a wide margin of error. Skillful use of digitalis requires careful study in every case. Standardization of the drug and the establishment of satisfactory clinical criteria for therapeutic action have, in large measure, eliminated the necessity for inducing toxic effects in order to be certain that enough has been given. The oft quoted dictum of Withering—"let it be given until it either acts on the kidneys, the stomach, the pulse, or the bowels"—no longer holds good with respect to stomach and bowels. Deliberately to poison the patient is not the goal of modern therapy.

Yet, in spite of reasonable care, toxic effects occasionally are induced. They must be watched for and, immediately upon the appearance of one of them, the drug should be discontinued or the dosage curtailed. Nausea, vomiting, headache, diarrhea and the occurrence of premature contractions are among the earlier evidences of intoxication. Mental confusion and visual disturbances are less frequently encountered. In the more advanced stages of poisoning, auricular fibrillation, auriculoventricular heart block and ventricular tachycardia may occur. Ventricular tachycardia is of particular significance, for giving more digitalis, after it has appeared, can convert it into ventricular fibrillation and cause sudden death.

Squill Prepared from the bulb of the sea onion, squill is one of the oldest medicinal agents. The earliest reference to it is found in a prescription contained in the Ebers papyrus, about 1500 B.C. For a long time it fell into disuse, apparently because of its tendency to cause nausea and vomiting. It enjoyed renewed waves of popularity, first in the middle of the eighteenth century, largely through the writings of van Swieten, and again, in the past 15 years, as a result of the isolation of various so-called "active principles." Most of these, however, have been only a little purer than the crude extracts, and because of their poor absorption from the

gastrointestinal tract they have rightly been regarded as undesirable substitutes for digitalis

Recently, by modifying the methods of extraction, a new preparation of squill has been made and is now marketed under the trade name, "Urginin." It is a mixture, in approximately equal proportions, of two of the active, water-insoluble glucosides—crystalline scillonin A and amorphous scillonin B. For oral use, it is put up in tablets containing 0.5 mg. each.

A clinical study of urginin was made during the past year in our department at the Presbyterian Hospital, by Chamberlain and Levy.⁵ It was found that, in patients with cardiac insufficiency, urginin exerted an action on the heart like that of digitalis. The effects were noted in the presence of regular rhythm as well as when the auricles were fibrillating. The therapeutic potency of urginin, in terms of cat units, was about one-half that of digitalis. Thus, approximately two cat units of urginin were required to induce effects, both therapeutic and toxic, comparable to those induced by one cat unit of digitalis. This difference in activity may be ascribed to less complete absorption or more rapid elimination in the case of urginin.

A satisfactory scheme of dosage, when no digitalis or urginin has been given for at least ten days preceding, was 1.5 mg. (3 tablets) three times a day after meals for two days, 1.0 mg. (2 tablets) twice daily until the desired effects were produced. The daily maintenance dose ranged from 0.5 to 2.0 mg., the average was 1.0 mg. (2 tablets).

Toxic effects noted were nausea, vomiting, diarrhea, transient auricular fibrillation, auriculoventricular nodal rhythm and varying degrees of heart block. But every patient without previous nausea was able to retain urginin if given after a meal in amounts not exceeding 1.5 mg. (3 tablets). Premature beats as evidence of intoxication were not observed.

The effects on the electrocardiogram were similar to those seen after digitalis.

It was concluded that urginin is an effective cardiac remedy. It offers no advantages over digitalis with respect to its action in myocardial insufficiency. But it serves a purpose in that occasionally, patients in whom digitalis induces nausea, vomiting or diarrhea, are able to take urginin without suffering from unpleasant symptoms. It may be useful also when a patient harbors an unfounded prejudice against the use of digitalis.

Strophanthin Because of the variability with which strophanthus is absorbed from the gastrointestinal tract, it is unsuitable for oral administration. Crystalline strophanthin (ouabain), derived from the seeds of *Strophanthus gratus*, is particularly useful for intravenous injection, because its crystalline character and known chemical composition make accurate dosage possible. An initial effect is apparent in from 5 to 20 minutes, the maximum effect in from 15 to 50 minutes.²⁸ If given in fractional doses, it may be administered safely to patients with auricular fibrillation with rapidly beating ventricles, who have not received digitalis within a week.

In them, ventricular rate can be used as a guide of effect. Greater care is necessary when it is given in the presence of regular sinus rhythm, when clinical improvement is the only criterion of full therapeutic effect. In those occasional instances when rapid action seems necessary, 0.5 mg. may be injected at the first dose, to be followed at intervals of one hour or more by 0.1 or 0.2 mg., up to a total dose of 1.0 mg. Treatment may then be continued by the use of digitalis, given by mouth, by rectum or by intramuscular injection.

Amorphous strophanthin, obtained from *Strophanthus kombé* or *luspidus*, is less uniform in composition and is not superior to the various aqueous preparations of digitalis.

Diuretics (a) *The xanthine group* Often rest in bed, curtailment of fluid and salt intake and the exhibition of digitalis promote diuresis and relieve edema. If, after these measures have been tried, there is evidence of continued retention of fluid in the tissues, diuretic drugs are indicated.¹⁶ For use by mouth a member of the xanthine group may be given.²⁵ Theobromine sodium-salicylate (diuretin) is one of the most valuable because of its relatively slight toxicity. It may be taken in powder or tablet form, in doses of 1.0 gm. (15 gr.), three or four times a day for two or three days, and then repeated at intervals of several days. Theophylline (theocin) may be similarly used in doses of 0.2 gm. (3 gr.) three or four times a day, but is more likely to upset the digestion. Theobromine-calcium salicylate (theocalcin) is a third member of the series, to be given in doses of 1.0 gm. (15 gr.) three or four times a day.⁴⁰ Theocalcin, being well tolerated, is of particular value when it is desired to maintain mild diuresis over a period of days or weeks.

(b) *The mercurials* Mercupurin and salyrgan have largely supplanted the xanthines^{8, 9, 33}. They are more rapid in action and more potent, yet relatively non-toxic. Renal irritation is rarely observed. They are given preferably by intravenous injection, in doses of 1 to 3 cc., the smaller amount being injected first to test the patient for possible idiosyncrasy to mercury. The injection may be repeated at intervals of four to six days when required. Mercupurin, which is a combination of theophylline with mercury, is less irritating to the tissues than salyrgan and can be given intramuscularly, if necessary. Both preparations are available in the form of suppositories,* they are somewhat less effective when given by rectum. The action of the mercurials may be enhanced by administering ammonium chloride or ammonium nitrate for from 24 to 48 hours prior to using the diuretic. These "acid producing" salts are best tolerated in the form of enteric coated pills of 0.5 gm. (7½ gr.) each. As much as 8 to 10 gm. of one or the other must be given in 24 hours, in divided doses, to be effective.¹⁷ Usually mercury alone is adequate, the tendency for the am-

* In the case of mercupurin, the suppositories do not contain theophylline and are known as "mercurin."

monium compounds to cause nausea and vomiting when taken in such large amounts, limits their clinical usefulness

The xanthines, according to the best evidence, increase glomerular filtration, the mercurials diminish tubular reabsorption. Since these two groups of substances thus differ in their mode of action, they may sometimes be used alternately to advantage

Sedatives The late Sir James Mackenzie has wisely said that "little benefit is likely to arise from treatment so long as a patient is worried or sleepless." The cardiac patient who has tossed about, harassed by dyspnea, awakens from a sound sleep refreshed and encouraged, after a hypodermic injection of 15 mg ($\frac{1}{4}$ gr) of morphine sulphate or 20 mg ($\frac{1}{3}$ gr) of pantopon. This may be repeated for several nights, or even during the day, until other measures have so improved the circulation that milder sedatives will serve, or none are required. One of the barbituric acid derivatives, such as phenobarbital, or a bromide mixture, given three or four times daily, will often allay restlessness. For insomnia, a barbiturate, such as sodium amytal or nembutal, will assure comfortable nights. A tranquil frame of mind is essential for proper relaxation and cooperation.

Cathartics Vigorous purging, with evacuation of copious watery stools, is no longer regarded as good practice. Fluid can be eliminated more readily and with less discomfort through the kidneys. The frequent use of bedpan or commode is tiring and requires effort at a time when rest is of first importance. Mild daily catharsis to prevent clogging of the intestinal tract is desirable. At the start, a dose of magnesium sulphate or compound jalap powder rids the bowel of accumulated waste, later, milder cathartics, such as cascara, are effectual, aided, if necessary, by a small, bland enema.

Glucose The intravenous injection of hypertonic glucose solution has been recommended, particularly by European authors. Sometimes it appears to help in initiating improvement when other measures have failed. The sugar is a nutrient for the myocardium, exerts a diuretic action and sometimes aids in relieving frequent paroxysms of dyspnea. From 50 to 100 cc of a 50 per cent solution are injected once or twice daily for several days.

Oxygen By definition, a drug is any substance used medicinally. Though administered by inhalation a gas falls into this category. Myocardial insufficiency is often accompanied by a state of marked anoxemia, this can be relieved by increasing the oxygen content of the inspired air to 50 per cent or more.¹ There result elevation of the oxygen saturation of the blood to normal, decrease in pulmonary ventilation and increase in the carbon dioxide concentration of the expired air. The heart rate becomes slower, dyspnea is relieved, cyanosis disappears, as does Cheyne-Stokes respiration, if present. The patient is less restless and within 24 hours may be able to sleep without the aid of narcotics. Part of the burden of a failing heart is lightened. In cases of chronic failure, not yielding to other forms of

therapy, residence in an oxygen tent or chamber over a period of days, or even weeks, has occasionally served to promote diuresis and by so doing, has started a chain of events leading to the recovery of compensation.

Patients with active rheumatic carditis, in our experience, have not responded favorably. Those in whom failure was due to coronary heart disease or hypertension have done well. Prolonged residence in an oxygen chamber has also been found useful in preparing persons with cardiac insufficiency for operative procedures. Cases of hyperthyroidism have been conspicuous in this group. The technic of oxygen therapy need not be given in detail here. The tent is now a familiar apparatus and is quite generally available. For prolonged periods, the chamber is more comfortable, though expensive to install and operate. The nasal catheter may be employed as a measure of moderate effectiveness. The mask recently described by Barach is still undergoing trial.

CARDIAC PAIN

Paroxysmal pain in the chest may be due to a variety of causes. Upon precise definition of etiology will depend the form of therapy. These remarks will be confined to a consideration of the discomfort commonly referred to as anginal, and due, in most instances, to atherosclerosis of the coronary arteries.

The Nitrites An attack will usually subside within a few minutes on the cessation of activity or the passing of an emotional upset. Judicious use of one of the nitrites affords prompt symptomatic relief, due to reduction in systemic arterial pressure as well as to dilatation of the coronary arteries. Nitroglycerine is convenient because it can be carried as a tablet, which should be thoroughly chewed before swallowing. A small dose, 0.3 to 0.4 mg ($\frac{1}{200}$ to $\frac{1}{150}$ gr.) often suffices and may not cause the flushing and headache sometimes so annoying after the larger and more commonly used tablet of 0.6 mg ($\frac{1}{100}$ gr.). There are cases in which only the larger dose is effective. It is important to insist that nitroglycerine tablets be fresh, after they have been exposed to the air for six to eight weeks, their strength deteriorates. The odor of amyl nitrite, in the form of pearls, has made it less popular than the nitroglycerine tablet. When an attack persists for more than an hour and is not relieved by nitrite, particularly if this is contrary to previous experience, occlusion of a coronary branch should be suspected.

The value of nitroglycerine as a prophylactic, suggested by the Englishman, Leech, in 1893, is not sufficiently appreciated. It was first called to my attention by Professor K. F. Wenckebach, of Vienna, a number of years ago. If a tablet or, if necessary two, be taken prior to anticipated effort or nervous strain, the activity can often be carried through to a painless conclusion. There is no harm in repeating the dose several times during the day. I have seen patients who have taken from 15 to 20 tablets of nitroglycerine daily over a period of years, without apparent harm and with no

loss in effectiveness. In my hands, the routine use of the nitrites, given at regular intervals during the day, has not proved as successful as when necessity or prevention served as indications.

The continued administration of those nitrites having a more prolonged action sometimes leads to marked lowering of blood pressure and syncope. If nocturnal attacks are troublesome, erythrol-tetranitrate, 30 mg ($\frac{1}{2}$ gr) may be taken immediately before retiring, the effect lasts for four or five hours and sometimes makes undisturbed sleep possible.

Sedatives The patient subject to anginal attacks is apprehensive. Mild sedatives produce a more equable state of mind and lower the threshold for pain. Phenobarbital, 15 to 30 mg ($\frac{1}{4}$ to $\frac{1}{2}$ gr) or a mixture containing 0.6 to 1.0 gm (10 to 15 gr) of bromide serves well in this capacity, and may be continued intermittently or continuously for weeks or months.

The Xanthines as Coronary Dilators Derivatives of theophylline and theobromine enjoy wide popularity for prolonged, daily administration. They are prescribed in the belief that they cause dilatation of the coronary arteries, prevent spasmodic contractions of these vessels and augment the flow of blood through the myocardium. There is at present disagreement as to their value, based both on laboratory and clinical studies. Smith and his collaborators, working with theophylline-ethylenediamine (aminophyllin) have found that in normal dogs, after ligation of a coronary artery the size of the infarct produced was smaller when the drug was given than in controls.¹² Gold and his co-workers¹⁵ were unable to confirm these results in cats. Wiggers and Green,³¹ using a different technic, concluded that "an increase in collateral circulation sufficient to be of functional use cannot be attained by use of vasodilating drugs after complete coronary occlusion." Whether these observations are applicable to the diseased human heart has not been demonstrated.

After administering members of this group of drugs to patients, and using adequate controls, different clinicians have reached opposite conclusions. Some, including Evans and Hoyle,¹⁰ and Gold, Kwit and Otto,¹¹ have stated that the xanthines exert no specific action which is useful in the routine treatment of cardiac pain. Others have been impressed by the favorable results. In a recent study, Brown and Riseman³ have determined the comparative value of eleven preparations, as judged by the usual clinical criteria, and also by measuring the amount of work, under standardized conditions, which could be done before the appearance of cardiac pain. They found that not all patients respond favorably to purines, but they offer no method of distinguishing between those who do and those who do not. Each preparation was given four times daily—on arising, after lunch and supper, and at bedtime. The order of effectiveness and the individual doses were: theophylline with sodium acetate, 0.25 gm (4 gr), theobromine with sodium acetate, 0.5 gm (7½ gr), theophylline with calcium salicylate 0.5 gm (7½ gr), theophylline with ethylenediamine 0.2 gm (3 gr).

The number and intensity of attacks of anginal pain are subject to wide variations, over a period of months or years, in the same person. Rest, adaptation to limitations, and acquisition of emotional stability often result in great symptomatic improvement in a relatively short time. Appraisal of the therapeutic result based upon the patient's own account is subject to error, the standardized exercise tolerance test, though partially objective, likewise depends for its end-point upon the sensations of the individual tested. In the light of such conflicting evidence, final judgment as to the virtues of the xanthines must be deferred. It is indeed questionable whether they accomplish any good.

Organ and Tissue Extracts A number of these have been tried, both by mouth and by hypodermic injection. I have never observed any benefit from their use.

ACUTE CORONARY OCCLUSION

Abiupt closure of a coronary branch, in its early stages, is a medical emergency. Complete rest and relief of pain by generous doses of morphine are the immediate requirements. It is now generally accepted that digitalis, in the absence of signs of cardiac insufficiency, should not be given. If congestive failure develops, or the attack is accompanied by the onset of auricular fibrillation or flutter, with rapid ventricular rate, it must be used in effective amounts, but cautiously. Digitalis is a cardiac stimulant, causing increased force of muscular contraction, the heart which is the site of recent infarction needs rest. The danger of causing rupture of the ventricle by the use of digitalis has been over-emphasized, but the possibility of inducing ventricular fibrillation is real, particularly after the acute phase has passed and the stage of repair is in progress^{2,13}.

If pain is severe or the signs of anoxemia are manifest, administration of oxygen, in concentration of 50 per cent, preferably in a tent, is indicated. Discomfort is lessened and the failing heart is often tided over a critical period. As pointed out by Levy and Barach²² in 1930, "in certain instances, effective use of oxygen may be responsible for the saving of life."

For collapse, caffeine sodium-benzoate, in doses of 0.3 to 0.5 gm (5 to 7½ gr), may be injected into a vein. Should nourishment be poorly taken or vomiting persist, hypertonic glucose solution, 50 per cent, is sometimes helpful. From 50 to 100 cc are given intravenously once or twice daily for several days.

The treatment of various cardiac irregularities which may occur as complications is considered in the following section.

CARDIAC ARRHYTHMIAS

Auricular Fibrillation In this form of irregularity, in which a circus movement travels an irregular course about the mouths of the great veins, the ventricles usually beat rapidly. Fibrillation of the auricles may be

paroxysmal or permanent. As a rule, it occurs in a diseased heart, most frequently in association with mitral stenosis, under these conditions, it is an expression of myocardial insufficiency and auricular dilatation. Occasionally it is observed in the absence of organic cardiac disease, due to toxic influences or neurogenic disturbances. No matter what the etiology, the first aim of treatment is to slow the ventricular rate. For this purpose, digitalis in full doses is dramatically effective, particularly in rheumatic and coronary heart disease. In cases with toxemia due to bacterial poisons, and in hyperthyroidism, slowing of rate is relatively slight.

When fibrillation is of recent onset, administration of digitalis may be followed by resumption of regular sinus rhythm, due to betterment in cardiac function. Should fibrillation persist, the rate should be brought to a level ranging between 70 and 80, at rest, and held there by proper adjustment of a daily maintenance ration. Patients with permanent auricular fibrillation, in whom the heart rate, undigitalized, is above 80, must take digitalis for the balance of their lives.

In certain cases, normal rhythm can be restored by the use of quinidine.⁴ Accumulated experience has shown that the number suitable for the use of this drug is limited. There are dangers from its administration.²⁰ Such discomforts as tinnitus, nausea, vomiting or diarrhea, though unpleasant, are of minor import. But induction of heart failure, syncope, collapse, embolic phenomena and sudden death are untoward effects which must be considered whenever quinidine is given. The careful selection of suitable subjects minimizes the hazards. Unfavorable criteria are idiosyncrasy to cinchona derivatives, fibrillation of long standing, cardiac enlargement, mitral stenosis, active carditis, cardiac insufficiency, previous occurrence of emboli to lungs or systemic arteries, complete heart block, bundle branch block, hyperthyroidism. It is at once apparent that only a small group is left. Indications favoring its use are fibrillation of recent onset, absence of cardiac enlargement, no valvular disease, fibrillation persisting after subtotal thyroidectomy for hyperthyroidism.

Most patients with organic heart disease and auricular fibrillation of long standing (longer than six months) are not greatly improved by restoration of normal rhythm. There is always the possibility, and indeed, the likelihood, that the irregularity will recur, with the sudden onset of a rapid ventricular rate. This requires another period of rest and quinidine therapy. With continuous digitalis dosage, the heart is stabilized and the rate is controlled. The possibility of the occurrence of upsetting episodes at inopportune moments is eliminated. Occasionally, however, when all the usual measures have proved unavailing in combating failure, restoration of normal rhythm may serve to turn the tide, in these rare instances, quinidine may be given a trial.

Before giving quinidine, congestive failure, if present, should be controlled by digitalis, and the ventricular rate should be retarded. The treatment should be carried out with the patient in bed, under careful observation,

preferably with electrocardiographic control. This form of therapy is not recommended for ambulatory cases.

A satisfactory scheme of treatment is as follows, the individual doses being given, by mouth, at intervals of two hours. *First day*, two doses of 0.2 gm (3 gr) each, these are to test for a possible idiosyncrasy to cinchona. Normal rhythm may occasionally ensue from this small, preliminary dosage. *Second day*, three doses of 0.4 gm (6 gr). *Third day*, four doses of 0.4 gm. *Fourth and succeeding days*, five doses of 0.4 gm. Larger amounts have been used but are not without added risk. The treatment may be continued for a week, though usually, a successful result, if obtainable, is accomplished in from four to six days. If it is necessary to prolong treatment beyond this period, normal rhythm, even though restored, is often not maintained. In a few cases, six to eight doses in a day have succeeded when five have failed. Intravenous injection of quinidine is inadvisable, several fatalities have followed this procedure.

After restoration of normal rhythm, it is desirable to continue with small doses of 0.2 gm (3 gr) three times daily, for several weeks. These tend to prevent relapse. Such amounts, or even larger doses, if necessary (0.4 gm three or four times daily), may be taken for weeks or months without harm or discomfort. A similar plan may be followed, often with conspicuous success, in cases of paroxysmal auricular fibrillation to prevent the onset of attacks. If these recur at frequent intervals, it is best to encourage permanent fibrillation and to control ventricular rate with digitalis.

Auricular Flutter. This is treated with digitalis in the same manner as described for fibrillation. Usually, full dosage is followed by the onset of fibrillation, with subsequent transition to normal rhythm. If flutter persists, quinidine may be tried, but the results, as a rule, are better with the foxglove. Should flutter be converted to fibrillation and normal rhythm not be resumed, quinidine may be used with good effect. There are occasional instances of flutter which are resistant to drug therapy. If the ventricular rate is controlled by digitalis, the patients are able to carry on their usual activities, provided the myocardium is functionally adequate. In several such cases, normal rhythm has been resumed spontaneously, for no apparent reason, after the lapse of months or years.

Paroxysmal Tachycardia. If the attacks are short and infrequent, no treatment is necessary. For the longer paroxysms, recurring at short intervals, simple measures should be tried, such as carotid or ocular pressure, change in posture, the induction of vomiting or forced respiration. Should these prove unsuccessful in terminating the bout, acetyl-B-methylcholine (mecholyl) may be injected hypodermically, in a dose of 20 to 40 mg. It is a powerful stimulant of the parasympathetic nerves. Starr,²⁸ who has written extensively concerning its use, has had excellent results, and these we have been able to confirm. The attack usually ceases in from one to twelve minutes. Unpleasant symptoms are common, these are dyspnea, substernal pain, vomiting, sweating, flushing and salivation. Atropine, 1/2

mg given intravenously, will counteract the action of acetyl-B-methylcholine almost immediately, and may be given if the reaction is severe. Attacks of auricular or supraventricular origin are usually stopped by the drug alone. If this is insufficient, carotid pressure during the drug's action is sometimes successful. It is not a dangerous remedy, but it should be used with caution in patients with asthma and in those suffering from conditions responding to epinephrine, which is a physiological antagonist of the choline.

Quinidine, given by mouth, is occasionally effectual in bringing about reversion to normal rhythm, particularly when the arrhythmia is of the ventricular type¹⁸. In rare cases an attack is terminated by the intravenous injection of strophanthin. Digitalis or strophanthin must not be given if the tachycardia is of ventricular origin, because of the danger of inducing ventricular fibrillation.

Syrup of ipecac, 8 to 16 c.c. (2 to 4 teaspoonfuls), may be taken orally to induce nausea or vomiting. This is an unpleasant measure, but, by reflex vagal stimulation, it sometimes terminates an attack.

The prevention of paroxysms by drugs is uncertain. Quinidine, in small doses (0.2 gm. three or four times a day) is the most valuable remedy and may be continued, if effective, for an indefinite time. Digitalization, with subsequent daily maintenance rationing, may likewise be tried. Sedatives, in cases in which nervous influences play a part in precipitating attacks, lessen discomfort and lower the threshold for disturbing factors.

Complete Heart Block Permanent heart block, unless accompanied by heart failure, rarely requires treatment. In certain instances, ventricular standstill or paroxysms of ventricular fibrillation cause dizziness, syncope or convulsive seizures (Stokes-Adams syndrome). It is necessary to know which mechanism is responsible for these attacks in order to carry out appropriate therapy. When ventricular asystole occurs frequently and is of sufficiently long duration to produce the symptoms of cerebral anemia, epinephrine is the best preventive¹¹. It is given in doses of 0.5 to 1 c.c. (8 to 15 minims) of the 1:1000 solution, by subcutaneous or intramuscular injection. The dose may be repeated as often as every two hours, if necessary. On rare occasions, if ventricular standstill is prolonged, intracardiac injection of epinephrine may save life. When the attacks are due to ventricular fibrillation, epinephrine is contraindicated, for it may perpetuate the mechanism and cause death.

If ventricular standstill tends to recur, ephedrine sulphate is sometimes partially or wholly effective as a prophylactic³⁷. Its action is similar to that of epinephrine, but is of longer duration. Ephedrine is given by mouth, in doses of 30 mg. ($\frac{1}{2}$ gr.) three or four times a day. Barium chloride, because it increases the irritability of the ventricles, and so lessens the likelihood of standstill, has been employed successfully in a few cases⁹; in patients under my observation, it has been less effective than ephedrine.

It may be given by mouth in doses of 30 mg ($\frac{1}{2}$ gr) three or four times a day

In the presence of heart block, quinidine should not be given, since there is some evidence that disturbances in the conduction system favor the development of ventricular fibrillation

MISCELLANEOUS CONDITIONS

In *diabetes mellitus*, coronary sclerosis is frequently present. Insulin both by causing hypoglycemia and by sympathetic stimulation, places an added burden of work upon the heart and sometimes induces paroxysms of anginal pain. In elderly diabetics, therefore, insulin should be given with caution, it may cause acute coronary insufficiency and sudden death. It is wiser, in many of these patients, to attempt to control hyperglycemia by dietary measures, even though the urine shows a faint reducing reaction and the level of the blood sugar is somewhat elevated³²

The facts concerning the value of intensive anti-luetic therapy in *aortic syphilis* are not yet fully known²⁶⁻²⁷. It is well to keep in mind two points: first, the cardiologist must have cognizance of the specific nature of the lesions in the heart, second, the syphilologist must appreciate the limitations placed upon anti-luetic treatment by the cardiac disability. As Wile³⁵ has phrased it in his "therapeutic paradox": "the patient gets well or better of his syphilis, but may die as the result of the dispersion of his syphilitic cardiac lesion". Particularly when involvement of the orifices of the coronary arteries is suspected, the arsenical preparations must be given with great caution, in the judgment of many, it is best, under these circumstances, not to use them at all²¹. Bismuth, mercury and iodide usually can be given with safety.

The use of digitalis in *lobar pneumonia* has occasioned wide differences of opinion. Some have stated that to employ it is dangerous and actually does harm. Others have maintained that every patient with pneumonia should receive it. As a matter of fact, circulatory weakness in pneumonia is not primarily of cardiac origin, the routine use of digitalis, therefore, is not sound practice. The situation was summed up by Cohn in 1935, after a critical analytical study⁷. He concluded that giving digitalis does not seem to influence the course of events in uncomplicated lobar pneumonia. But when congestive failure appears, as it may in patients with cardiac disease, or when auricular fibrillation or flutter occurs, the action of digitalis appears to be beneficial. Under these circumstances, it is sometimes life-saving. The outcome in lobar pneumonia, however, depends primarily upon the severity of the disease itself, and this is determined by the presence of bacteremia, the number of lobes involved, and the existence of complications.

CONCLUSION

It is apparent, even from this incomplete discussion, that there are indeed many remedies which can be applied, under different circumstances, in disorders of the heart. Precisely when to prescribe each drug, how much to give, and when to stop, are matters of vital importance. Judgment, based on close observation and experience, is sometimes difficult. Because of the large number of variable factors which modify the picture of disease in human beings, it is not possible to carry out treatment according to a fixed formula. An attempt has been made to describe some of the medicinal tools which have been found useful, and to indicate certain ways in which they may be employed with benefit. Upon the skill of the medical workman will depend, in large measure, the successful outcome of his therapeutic efforts.

THE USE OF THE MERCURIAL SUPPOSITORY AS A DIURETIC ¹

By JAMES FLEXNER, M D , *New York, N Y*

INTRODUCTION

ORGANIC mercurial compounds have been recognized as having valuable diuretic properties since 1920 ¹ and have been used with increasing frequency since the introduction of salyrgan in 1924 ² Later mercupurin (novurit), neptal and mercurosol were used These drugs proved to be of great benefit in the treatment of cardiac edema, of moderate assistance in the management of nephrotic edema, and of lesser therapeutic value in the edema and ascites of hepatic cirrhosis In addition to the known limitations, the drugs were objectionable because they were mercurials and thus renal irritants Great care was therefore necessary in controlling their administration to avoid kidney damage They were effective only when given intravenously or intramuscularly which entailed some discomfort, and occasionally slough or venous thrombosis as a complication

In an effort to avoid these latter difficulties, salyrgan has been administered orally, but with poor results ³ In 1931, Engel and Epstein used salyrgan rectally in 100 cc of water with fair results ⁴ More recently, rectal suppositories containing 0.5 gm of novurit [†] were made available abroad The active principle was a sodium salt of an organic mercurial combined with theophylline ⁵ In this country similar (mercurin) suppositories have been offered containing 0.5 gm of the organic salt found in mercupurin, without theophylline Even more recently salyrgan suppositories containing theophylline have become available Clinical investigators were immediately interested in the efficiency of these preparations

Parkinson and Thomson ⁵ made a study of novurit suppository, novurit and salyrgan (each with and without ammonium chloride) They concluded that "novurit suppository is an effective and safe diuretic" and that all three agents are more effective after the administration of ammonium chloride In the 10 cases reported they avoided the use of digitalis during their determinations Fulton ⁶ made a similar study using mercurin suppository, mercupurin and salyrgan on 25 cases and reported favorable results with mercurin suppositories Herrmann and Decherd ⁷ published some studies on diuretics including the satisfactory use of mercurin suppositories

* Received for publication December 20, 1937

From the Department of Medicine, New York Post-Graduate Medical School and Hospital, New York, N Y

[†] Campbell Products, Inc, manufacturers of mercupurin and mercurin suppositories in this country, assure us that their products are identical with novurit and novurit suppositories According to their statement, the term "novurit suppository" is misleading because the suppositories contain no theophylline

METHOD AND SELECTION OF CASES

On the wards at New York Post-Graduate Hospital mercurin suppositories have been used on one or more occasions in 12 cases of edema. Of these 12 cases, the edema was due to congestive heart failure in 10, while cirrhosis of the liver was considered to be the causative factor in the other two. In the 10 cases of cardiac decompensation the mercurin suppositories were used in conjunction with the routine treatment of bed rest, sedation, digitalis and ammonium chloride. In three of the cases intravenous mercurials were employed also, and a comparison of the effectiveness of the parenteral and rectal route is available.

In the two cases of cirrhosis of the liver mercurial diuretics were administered by both the above routes, in one case, both before and after ammonium chloride ingestion.

These cases are briefly reported below. The therapy used is indicated by the routine just mentioned and is apparent in the table and figures. The only details included below are those directly relating to the problem, namely, whether mercurial suppositories are an aid in the treatment of edema.

EXPERIMENTAL OBSERVATIONS AND DISCUSSION

Case 1 (Table 1) A. B., female, aged 44, was admitted complaining of swelling of abdomen and legs, and "weakness around her heart" for the preceding two weeks. She had been short of breath for two months. Her illness began two years previously with fever, swelling of the joints and "heart trouble." Physical examination revealed a slight degree of dyspnea and orthopnea. Moist râles were present in the bases of both lungs. Her heart was moderately enlarged to the left. A shock and systolic thrill were felt at the apex. A systolic murmur was heard at the apex, the pulmonary second sound was slightly accentuated. The heart rate varied from 96 to 108 per minute and was totally irregular. Blood pressure was 136 systolic and 82 diastolic. The abdomen was moderately distended, with signs of free fluid. The lower extremities showed edema grade one plus.

Case 2 (Table 1) H. I., male, aged 47, was admitted because of shortness of breath and swelling of the abdomen. As a young man (25 years before) he had had rheumatic joint and heart disease and had been given salicylates. He had been entirely well until the week before examination when he noted the above symptoms which became progressively worse. He was unable to sleep at night because of shortness of breath and coughing spells. Although no chest pain was present the patient complained of a pounding heart. Physical examination revealed the patient to be dyspneic and orthopneic. The teeth were carious and infected. The chest was dull over both bases, râles were present, and breath sounds slightly decreased. The heart was somewhat enlarged. There was a systolic murmur at the apex and the pulmonic second sound was accentuated. The apex rate was 126, radial rate 80 with total irregularity, blood pressure 160 systolic and 100 diastolic. The abdomen was obese. The liver was palpated down to the umbilicus and found to be firm and tender. The spleen was not palpated and no ascites was apparent. Ankle edema was absent.

A mercurin suppository was given on the second day but no diuresis was apparent until three days later after ammonium chloride gr 120 had been given daily.

Case 3 (Figure 1) M M, female, aged 44, was admitted complaining of shortness of breath, swelling of feet and ankles and of some pain in the abdomen. Three years before the patient first began having asthmatic attacks at night. The attacks were severe and the patient was obliged to sit up to get her breath. Her feet and ankles had been swollen at times for ten months. This was her second admission within six months. She had been receiving digitalis in the clinic. She had precipitated her present cardiac decompensation by over-exertion.

FIG 1 *Case 3* Aged 44, F Hypertensive cardiovascular disease

Physical examination revealed marked dyspnea, edema and ascites. Her chest was dull on the right to the spine of the scapula. Râles were heard over both bases with decreased fremitus in the right base. The heart was enlarged to the left, a systolic blow was heard at the apex, auricular fibrillation was present with a rate of 92, the blood pressure was 190 systolic and 110 diastolic. The abdomen was greatly distended with fluid. The liver edge was tender and extended 8 cm below the costal margin. The spleen was not palpated. The legs were edematous to a maximum degree. A pustular eruption on an erythematous base was observed on both thighs.

A graphic presentation of this case (figure 1) shows that on her second day in bed, in response to increased digitalis, bed rest and a mercurin suppository, she had an output of 3,475 cc of urine. She had marked anasarca, cyanosis and dyspnea. On the fifth day her condition seemed more critical than on admission. Ammonium chloride gr 135 daily was begun and another suppository used, with a resultant urinary output of only 1,950 cc. However, on the fourth day of ammonium chloride, another mercurin suppository was followed by a diuresis of 8,750 cc. The ammonium chloride was continued and a mercurin suppository used on four subsequent occasions during the next three weeks and in each instance the output exceeded that of the fifth day. This patient on admission and for the first eight days in the hospital was so decompensated that one would expect all of her excretory mechanisms to be impaired sufficiently to induce an acidosis, however, on the second day of hospitalization the CO_2 combining power was 58.9 volumes per cent and on the ninth day after receiving ammonium chloride gr 135 daily for four days (the morning after the greatest urinary output) the CO_2 combining power was 73 volumes per cent (done in duplicate). Thirteen days later with continued ammonium chloride therapy, the CO_2 combining power was 63.3 volumes per cent and the increased urinary output was maintained.

Case 4 (Table 1) O. R., female, aged 51, was admitted for the second time within seven months complaining of shortness of breath, cough, blueness of the face after coughing, pain over the heart and swelling of the ankles. Upon physical examination the patient was found to be markedly obese (weight 233 lbs.), slightly cyanotic, and orthopneic. The chest was dull on percussion over both bases and moist rales were present. The heart was enlarged to the left. The pulse rate was 120, blood pressure 160 systolic and 100 diastolic. The abdomen was extremely obese. Ankle edema was graded one plus.

This patient received ammonium chloride gr 135 daily beginning the twenty-seventh day of hospitalization. After eight days of ammonium chloride medication the CO_2 combining power was 49.2 volumes per cent and after 16 days it was 52.2 volumes per cent. A mercurin suppository resulted in a marked diuresis on this day.

Case 5 (Figure 2) T. M., male, aged 51, had nocturnal cough for several months and these "asthmatic attacks" had been increasing in severity. For the past month he had been forced to use three pillows and was very short of breath upon the slightest exertion. He was conscious of his heart pounding with an occasional pronounced thump. His legs had been swelling for about six weeks. For the past two weeks he had had a sense of fullness in his upper abdomen which was most distressing. The patient was observed to be orthopneic and dyspneic. He had dullness and rales over both bases. His heart was enlarged to the left and was totally irregular in rhythm. There were no murmurs. The apical rate was 114 and the blood pressure 146 systolic and 76 diastolic. His liver was enlarged downward and tender. Sacral and ankle edema were graded three plus.

This patient received 1 cc of salyrgan intravenously on the first day which resulted in a very mild diuretic response (figure 2). After digitalis

and ammonium chloride therapy, however, excellent results were obtained with both mercurin suppository and intravenous salyrgan. In both these latter instances larger doses of the mercurials were given. In this case there also was a slight rise in the CO_2 combining power in the face of continued use of ammonium chloride, gr 90 daily. This observation was constant in the three cases in which these determinations were made.

Ethridge et al.⁸ found in studying the effect of inorganic salts on the diuretic action of salyrgan that the acidifying salts caused an increase in diuresis. They observed a moderate decrease in the CO_2 combining power

FIG 2 Case 5 Aged 51, M Arteriosclerotic heart disease

of the plasma of dogs three hours after the administration of ammonium chloride by stomach tube. They attributed the enhancement of the diuresis to this moderate acidosis.

Dennig et al.⁹ observed that patients who took large amounts of ammonium chloride daily developed a greater degree of acidosis on the second and third days of administration than subsequently even though the ingestion of the salt was continued.

Keith¹⁰ feels that the change in the CO_2 combining power is not of sufficient magnitude to account for the increase in diuresis when the acid

forming salts are given. He believes that the specific action of the acid radical is an important factor.

The findings reported in this protocol tend to minimize the importance of reduction of the CO_2 combining power.

Case 6 (Figure 3) A II, male, aged 62, had first noted shortness of breath six months prior to admission. Because of this complaint he had been forced to

FIG 3 Case 6 Aged 62, M Syphilitic and arteriosclerotic heart disease
 Case 7 Aged 30, M Hypertensive cardiovascular disease
 Case 8 Aged 67, M Arteriosclerotic heart disease
 Case 9 Aged 61, M Arteriosclerotic heart disease

limit his activity but despite this care his dyspnea became more severe. He had noticed edema of the ankles for two months. He had consulted his physician at the start of his complaints and the doctor had told him that his blood pressure was "195". The patient stated that at times he had spots before his eyes and roaring in his ears.

The patient was not acutely distressed. Upon examination a bony growth was found on the hard palate. His teeth were carious and the gums were infected. His

tonsils were enlarged. Râles were heard over the bases of both lungs. The heart was enlarged to the left and the apex rate was 110. The blood pressure was 190 systolic and 120 diastolic. The abdomen was obese and edema of the ankles was present, graded two plus. The blood Wassermann test was four plus on two occasions. Fluoroscopy revealed a diffuse dilatation of the aorta.

Case 7 (Figure 3) P. M., male, aged 30, first noticed shortness of breath one year prior to admission. He had been put to bed for 14 weeks. Digitalis was administered, but was discontinued when he was allowed to leave his bed. For the three weeks preceding admission he had suffered epigastric fullness, belching and constipation. He had a mild cough which caused pain in the right upper quadrant.

When observed the patient was sweating profusely although not in acute distress. He was moderately obese. Râles were present in both bases posteriorly. The heart was moderately enlarged to the left, the pulse was 115, gallop rhythm and an occasional extrasystole were noted. The blood pressure was 165 systolic and 135 diastolic. The abdomen was moderately obese and the edge of the liver was definitely palpable and quite tender. The lower margin of the spleen was felt at the costal margin. Edema of the lower extremities and over the sacrum was of moderate grade.

In case 5 (figure 2) and cases 6 and 7 (figure 3) a comparison between the efficacy of mercurin suppositories and intravenous mercurials may be drawn. An approximately equal degree of diuresis was obtained with each method, but a greater amount of mercury was administered in the suppositories.

Case 8 (Figure 3) H. M., male, aged 67, was brought into the hospital acutely ill with orthopnea and cough. He had had "bronchitis" for years, but, several weeks before, he complained of a moderately severe, non-radiating pain over the heart which had persisted for several days. Following the pain the bronchial symptoms became worse. On the night of admission the patient had a severe seizure of coughing with production of pink, foamy sputum and marked shortness of breath. His face became cyanotic and he appeared in great distress. The chest was emphysematous with a precordial bulge. Wet, rattling râles were present throughout both lungs. The heart was enlarged to the right and left, the rate was 120 and the rhythm totally irregular. The blood pressure was 130 systolic and 70 diastolic. The liver edge was palpated 4 cm. below the costal margin and was not tender. There was no edema. The patient responded promptly to venesection and stimulants. An electrocardiogram showed auricular fibrillation, and premature ventricular contractions, evidences of coronary occlusion were present. Fluoroscopic examination revealed a greatly enlarged heart and a diffuse, almost aneurysmal dilatation of the aorta. The blood Wassermann was repeatedly negative.

Case 9 (Figure 3) I. M., male, aged 61, complained of difficulty in breathing. He was a known mild diabetic and had had hay fever and "asthma" for 15 years. For the past year he had experienced gradually increasing weakness, dyspnea, and swelling of his ankles. Also he had complained of belching for the past three months. The patient was obviously dyspneic and coughed frequently. Fine râles were heard over the right side of the chest but no asthmatic wheeze was apparent. The heart was enlarged to the left and the tones were distant and muffled. An occasional extrasystole was present. The pulse was regular, rate 100, blood pressure 114 systolic and 70 diastolic. The abdomen was negative except for the liver which was easily palpated. Pitting edema was found upon examining the extremities. The diabetic state was found to be under control. The chest signs and respiratory symptoms disappeared in response to cardiac therapy.

Case 10 (Table 1) E. M., male, aged 44, stated that he had had an attack of rheumatic heart disease at the age of 35. At that time he had shown all the symptoms and signs of cardiac decompensation and had been told that he had murmurs. Later he was informed that his recovery was complete. A few weeks prior to his admission he had a mild cold which was followed by pounding of the heart, shortness of breath, and swelling of the extremities. The patient showed marked pallor, dyspnea and orthopnea. Rales were present throughout both lungs. The heart was enlarged to the left. Pulse rate was 140, rhythm totally irregular. The blood pressure was 135 systolic and 65 diastolic. The liver was palpable and tender. Extremities were edematous. No petechiae were found. The temperature was 101° F by rectum. An electrocardiogram proved the cardiac irregularity to be auricular fibrillation.

The urinalysis of this patient on admission yielded findings typical of chronic passive congestion. Specific gravity 1.020, albumin plus, 3-5 red blood cells per high power field (centrifuged). A mercurin suppository was given on the second day but the patient showed only a slight, if any, increase in urinary output and this questionable increase was delayed until 48 hours after the administration of ammonium chloride had been begun. A second mercurial suppository was given on the ninth day, and 48 hours after its administration (and six days of ammonium chloride therapy) the patient suddenly became disoriented, had thick speech and hyperpnea. He complained of double vision, and there was paralysis of the fourth cranial nerve. He was thought to have had a cerebral embolus. The urine the next day contained innumerable red blood cells, gross hematuria continued for a month and microscopic hematuria persisted until the patient's death. The patient had a rising blood pressure from 135 systolic and 65 diastolic to 184 systolic and 85 diastolic, a rising azotemia up to a level of urea nitrogen of 49 mg per cent, and of non-protein nitrogen of 75 mg per cent. The urea nitrogen to non-protein nitrogen ratio was 0.65. The blood cholesterol dropped from 185 mg per cent to 155 mg per cent, the CO combining power at the time of the acute episode was 29.6 volumes per cent. The specific gravity of the urine on 22 separate specimens ranged between 1.010 and 1.016. The anemia increased. The blood chemical data and the urinary findings at this time pointed to rapidly contracting kidneys such as are found in a fulminating type of diffuse glomerulo-nephritis. An intravenous urogram two weeks prior to death was unsuccessful because of inadequate concentration of the dye in the kidneys. The auricular fibrillation persisted as did the diplopia and the thick speech. The patient died 10 weeks following the first cerebral embolus. He complained of headache, lapsed into coma with stertorous breathing, hyperreflexia, increase in edema and multiple petechiae on the lower extremities. (These were the only petechiae ever observed during the patient's entire illness.) The patient died 24 hours later. Permission for autopsy was denied but the cause of death was thought to be a second cerebral embolus.

Keith¹⁰ pointed out that hematuria and renal insufficiency has occurred, though rarely, from the injection of organic mercurials. He also observed that ammonium chloride may induce a mild renal insufficiency which is usually temporary in duration.

Case 11 (Table 1) T. C., male, aged 33, had been a known luetic for 12 years. Six weeks prior to admission the patient had received the last of 12 doses of arsphenamine. For the 10 days preceding admission the patient complained of an increasing yellow tinge to his skin and of vague abdominal pain.

Physical examination was negative except for marked icterus and slight tenderness in the right upper quadrant. Chemical studies supported the history by indicating the presence of a toxic hepatitis. In the second week in the hospital the

patient complained of a distended abdomen and by the eighteenth day free fluid was detected. During the third week the patient called attention to discomfort in his rectum. Following the onset of the ascites, he had developed large, tender hemorrhoids.

Case 12 (Table 1) G. G., male, aged 58, had had pain in the upper abdomen for two months. The pain was not severe but annoying, and his "asthma" which he had had for several years became increasingly worse. He also had been aware of increase in his abdominal girth and his legs were markedly swollen. The patient's face was covered with spider telangiectases and it also had a slight icteric tinge. Rales were present throughout the chest. The heart was enlarged to the left and a systolic murmur was heard over the entire precordium. The pulse rate was 92 and regular, the blood pressure was 155 systolic and 85 diastolic. There was an umbilical hernia present and the abdomen was distended with fluid. The liver was firm, non-tender, and palpable on ballottement. The lower extremities were markedly edematous. The patient had large, tender, protruding hemorrhoids. During the course of treatment the rales and edema disappeared in response to cardiac therapy but the ascites increased. Frequent paracenteses were of only transient aid. The patient developed a psychosis during his illness with paranoid manifestations. Chemical studies revealed an icteric index ranging from 14 to 30, normal figures were found for urea nitrogen, amino acids, non-protein nitrogen and cholesterol. The cause of the persistent ascites was considered to be hepatic cirrhosis. The patient's course was downhill in spite of all therapy. Permission for autopsy was denied.

In cases 11 and 12 (patients with hepatic cirrhosis, ascites and hemorrhoids), the suppositories caused discomfort because of the rectal lesions. In case 11 the suppositories were expelled within 20 minutes because of the local distress. In this case, however, there was a diuresis but it may have resulted from the ammonium chloride which the patient also was receiving. In case 12 mercurin suppositories on four occasions failed to result in diuresis. Intravenous injection of 2 c.c. of mercupurin caused no increase in urinary output in one instance but on a subsequent injection an output of 2,050 c.c. was obtained. This patient was quite refractory and refused ammonium chloride in solution or as enteric coated pills. The ascites in cirrhosis cases does not respond well to mercurials intravenously and with impaired absorption and brief time of retention of the suppositories it is not surprising that the rectal route of mercury administration was not efficacious in these two cases.

SUMMARY

Mercurin suppositories were used on 20 occasions in 10 patients with varying degrees of cardiac decompensation. These patients were routinely treated by bed rest, sedation, digitalis and restricted fluid intake. In 17 instances (85 per cent) a diuresis ranging from 1,950 c.c. to 8,750 c.c. in 24 hours resulted from the use of the suppositories. In one of the failures (case 2, table 1) the diuresis was delayed following the suppository administration until the third day of ammonium chloride therapy. The other two failures were obtained in case 10 (table 1) which showed renal complications. Renal insufficiency followed the mercurial suppositories and

ammonium chloride administration in this case but the subsequent death apparently was caused by a cerebral embolus

In the two cases of hepatic cirrhosis studied, mercurin suppository did not seem to be the best form of mercury administration because of the rectal discomfort and the lack of consistent increase in urinary output

CONCLUSIONS

1 The mercurin suppository is an effective diuretic agent in selected cases

2 It is most efficacious when used in conjunction with ammonium chloride. Ammonium chloride is a valuable adjunct and in some cases essential to the production of a satisfactory diuresis. In three cases in which the CO_2 combining power was observed at intervals, ammonium chloride had a marked synergistic diuretic effect even though normal or elevated CO_2 combining powers were present

3 Mercury is a renal irritant and its use in any form should be carefully controlled by frequent urinalyses

SOME PUBLIC HEALTH ASPECTS OF UNDULANT FEVER *

By HAROLD G. NEWMAN, B S , A M , M D , *St Louis, Missouri*

IN this brief discussion undulant fever is treated as a public health problem in order to bring out a few points concerning the diseases in lower animals from which the human being derives his infection. It is felt that to many medical men more information concerning the manifestations of this disease in domestic animals will be of interest.

Considerable confusion exists over the terminology. Malta fever, undulant fever, brucellosis, brucelliasis, Mediterranean fever, Bang's disease and many other terms are employed. Similarly there has existed among bacteriologists considerable controversy over the classification and relationship of the bacteria present in the lower animals afflicted with this disease or group of diseases.

For practical purposes there seems to be enough agreement to permit calling this entire group of fevers the brucella group, reserving the term undulant fever for the clinical disease seen in man, which is apparently the same disease regardless of the source of infection. Similarly, there is considerable agreement as to the classification of the three main species of bacteria etiologically responsible. These are *Brucella melitensis* causing Malta fever in goats, *Brucella abortus* causing contagious abortion in cattle, and *Brucella suis* producing abortion disease in swine. As previously stated, infection with any of these three results in undulant fever in man and the disease appears to be the same regardless of its source.

Experimentally brucella infection can be produced in any warm blooded animal, but the three diseases mentioned above are the only ones with which we need be seriously concerned.

In America the milch goat can be dismissed as being a very minor factor in the spread of undulant fever, although a few cases have been traced to imported goats, and several years ago a serious outbreak occurred in the southwest where European goats had been introduced on a fairly large scale commercially.

Granting that this source is a minor one, the history of Malta fever is too interesting and has added too much to our knowledge of brucellosis in general to be disregarded completely. (Incidentally, the term Malta fever was objected to so strenuously by the Maltese that the League of Nations Health Organization changed the name to undulant fever in their official list of diseases.)

The fever has been known for centuries in Mediterranean countries. In fact Hippocrates described a fever which historians now recognize as being Malta fever. During the eighteenth and nineteenth centuries various accounts of the disease appeared and during the Crimean war considerable confusion existed due to the simul-

* Received for publication May 25 1937

From the Medical Service of St. Luke's Hospital, St. Louis, Missouri

taneous presence of Malta and typhoid fevers in the British troops. The disease was first found to have a specific etiology in 1886 when Colonel Bruce¹ described a small cocco-bacillus seen in sections of spleen and the following year isolated the bacillus from human cases found on the island of Malta. He seems to have been the first to name the organism *Micrococcus melitensis*.

The next big step in studying the disease took place in 1897 when Wright and Semple² showed that it could be diagnosed by agglutination with the blood serum of infected animals.

In 1904 a commission was appointed by the British admiralty, the war office and the civil government of Malta to study the problem. Among their most important findings may be listed the fact that over 40 per cent of the goats on the Island of Malta were infected and that a big percentage of these were eliminating virulent bacteria in their milk. Human cases were traced to drinking such milk. Many other cases were found in herdsmen and those handling the infected animals. Many of these were found to have been infected through skin abrasions contaminated with urine from infected goats, in which large numbers of organisms were found.

In the commission's final report they stated that the most common method of infection in man was by the ingestion of infective articles of food, mainly milk.

When we come to consider contagious abortion in cattle and swine we find a more serious source of danger to man. This disease in animals has been reported from every civilized country and in America it has long since surpassed tuberculosis of cattle as an economic problem. It is this point of great prevalence which I wish to emphasize for I am sure it is not generally appreciated by the medical profession. We are accustomed to regard undulant fever in man as a comparatively rare condition and thus may lose sight of the fact that the possibilities for infection are almost unlimited.

The various states cooperating with the Bureau of Animal Industry are at present engaged in a vast control program which includes blood testing of large groups of dairy cattle. Without quoting any mass of data, I should like to give the figures for Missouri for the two year period ending October 31, 1936. Approximately 52,000 herds were tested in this state and infection was found in over 16,000 of them. Out of 640,000 cattle tested, 52,000 were found to be infected. These figures indicate in general what was found for the entire country in which over twelve million cattle were tested during this period and approximately one million reactors were found.

In a short discussion it is impossible to give more than a sketchy outline of the disease in cattle. Briefly the outstanding feature, as the name implies, is actual abortion in the gravid animal. The abortion is brought about by active inflammation within the uterus and the fetal membranes. A given animal may abort one or more times and then usually develops enough immunity to carry subsequent pregnancies to term.

Unless the uterus becomes invaded with other organisms which produce metritis and future sterility, actual illness is not apparent. The severe constitutional upsets seen in the human do not occur in either cattle, swine or goats. The bacilli live a more or less innocent existence within the body of the animal and are spread to the outside world in the lochial discharges.

of the aborting animal, in the urine and feces, and through the milk where they appear continuously or in frequent showers. A microscopic mastitis without signs or symptoms is usually found in these animals. Rarely the male is found to react, the infection being present in the glandular systems, chiefly the testes. In cattle the disease spreads from animal to animal chiefly from contaminated pasturage or by means of infected food, the infection being spread chiefly by way of the gastrointestinal tract. The bacilli will remain alive and virulent for as long as four months in damp soil shielded from direct sunlight.

The disease in swine shows much the same clinical picture and needs no special mention.

Dr Alice Evans³ of the Dairy Division of the Bureau of Animal Industry was the first to point out the similarity between the *Micrococcus melitensis* of Bruce and the bacillus of contagious abortion first isolated by Professor Bernard Bang⁴ of Copenhagen in 1897 and now usually called the Bang bacillus. She showed that the two are so similar as to be indistinguishable by ordinary laboratory means. Regardless of the source of infection, undulant fever runs the same course in man and routine agglutination methods will not suffice to determine which species is present. How recent is the knowledge that abortion disease in cattle could result in undulant fever in man is shown by a statement made by Dr Evans in her 1918 article. In her discussion she states that "Since infection is dependent on the amount of infectious material, it may be that this difference in the number of bacteria in the milk of the two species of animals may account for our freedom from disease when cow's milk containing *Bacterium abortus* is consumed. On the other hand, are we sure that cases of glandular disease, or cases of abortion, or possibly diseases of the respiratory tract, may not sometimes occur among human subjects in this country as a result of drinking raw cow's milk?" This prophecy was made only 17 years ago and has proved only too true. We now know that brucella infection can and does attack every tissue and organ in the human mechanism. Ironically as it may seem, Dr Evans herself was soon to prove how accurate her own surmise was.

Since such abundant opportunity to become infected exists, we may well ask why more cases are not reported. One reason I am sure lies in the fact that many cases are never diagnosed. Many of the cases which are diagnosed have been treated for other things first. This is especially apt to occur in communities where laboratory facilities for making serological tests are not easily available. The tendency of the infection to produce tender and swollen joints makes it easy to confuse with arthritis. Many cases start with the step-ladder rise in temperature characteristic of typhoid. Chills with a daily rise in temperature are certainly suggestive of malaria and apt to be treated as such in the absence of proper blood examination. Another reason we do not see more of this disease is the fact that so much

milk consumed by the public is pasteurized. Proper pasteurization readily destroys the bacillus.

It is a well known fact, readily apparent clinically, that there is a great variation in the virulence of individual strains of the Bang bacillus found throughout the country. Occasionally a strain is encountered of such high virulence that practically every animal of breeding age in a herd will become infected and abort. At the other extreme is found a strain, isolated years ago by Huddelston, which he called an avirulent strain and which he used with impunity as a living vaccine in attempting to build up immunity in non-infected cows. This fact being true, whether an individual becomes infected probably depends to some extent upon how virulent a strain he encountered when the infected milk was consumed.

Infection with *Brucella suis* or the porcine strain is found chiefly in herdsmen, veterinarians, butchers and packing house workers who come into contact with infected animals or who handle the meat after such animals are slaughtered. In such cases infection probably enters through cuts and abrasions in the skin which have become soiled with the excreta of the living animal, or with the blood and tissue juices of the animals on their way through the various steps of packing house routine.

Undulant fever is diagnosed by the agglutination or complement fixation tests and by allergic skin reactions with culture filtrates such as the Brucellin of Huddelston. Cultural methods and guinea pig inoculation are valuable experimentally but too slow for routine clinical use. My own preference, based entirely upon tests in domestic animals, has always been for the complement fixation test in spite of its more involved technic. While it has now been practically discarded in favor of the much quicker and simpler agglutination test, I still have a feeling that it is the more accurate method. In man it is not uncommon to get a negative agglutination reaction on a patient known to be infected. In such a case the skin test will often be positive. On the other hand, positive agglutination does not always mean that the patient is actively infected. Some difference of opinion exists as to how low the dilution should be carried. Some laboratory technicians report any agglutination at all as being evidence of infection. In early work on Bang's disease in cattle, we disregarded agglutination in dilutions of $\frac{1}{320}$ or below as being false reactions. Ample clinical proof was available to support this stand.

It was formerly thought that agglutination in human serum might be due sometimes to ingestion of preformed antibodies present in milk since such antibodies are present in milk from practically all infected cows. This type of reaction has since been denied and the statement made that such antibodies cannot pass through the walls of the digestive tract. In this connection I should like to recall briefly an experiment I helped to conduct many years ago. We found routinely that just prior to calving most positively reacting cows lost their positive reaction and remained negative for

many weeks. The colostrum milk at this time, however, was found to be almost unbelievably rich in immune bodies. It appeared that the protein fraction of the blood serum which carried these immune bodies had become concentrated in the colostrum and stored there. When these cows calved, if such calves were bled and tested immediately, before nursing their mothers, their serum always gave a negative reaction. If kept permanently from their mothers such calves could be raised by hand on other milk and reached maturity without ever giving a positive reaction. If, however, they were allowed to nurse, blood serum drawn two or three hours later always gave a strongly positive reaction. Similarly, calves from negative mothers, if given colostrum rich in antibodies, would show the same thing. Of course, the digestive tract of a young calf is entirely different from that of a man but it is hard to see how these newborn animals could ingest virulent infection and immediately develop enough immune bodies of their own to give strong serological reactions two or three hours later. It seems more logical to believe that preformed antibodies did pass through the intestinal wall barrier. If virulent cultures were given by mouth or hypodermically 10 or 12 days had to elapse before immune bodies could be detected in the blood.

In the matter of treatment the veterinary profession has practically run the gamut of drug and biological products with but scant success. Dean Giltner, previously quoted as being an outstanding authority, stated in a recent publication that "Curative treatment of brucellosis by the use of drugs or chemical has signally failed." All manner of bacterines, vaccines and sera have been used with occasional encouraging results but nothing has been devised which can be generally counted on for definite results. This therapeutic failure has greatly stimulated control programs which have for their goal the ultimate elimination of the disease by destruction of less valuable animals and isolation of those reactors too valuable to sacrifice. Healthy progeny can be raised from infected stock if removed from sources of contagion prior to reaching breeding age. By means of wholesale blood testing and proper sanitation it is hoped to establish accredited abortion-free herds and eventually to rid the countries' dairy and beef herds of this malady. Cooperation on the part of stock breeders will eventually be gained through necessity. Even now it is becoming practically impossible for a breeder to sell a pure bred animal without a negative blood test. Certified milk can be placed on the market only if the animals supplying it can be shown to be free from tuberculosis and abortion disease. Rigid restrictions against interstate shipment of infected cattle are now in existence in most states. Such restrictions have gone a long way to correct abuses which formerly existed. That such programs must go forward against tremendous odds goes without saying, but marked progress is being made.

PROTAMINE-ZINC-INSULIN IN DIABETES¹

By E. PERRY McCULLAGH, M.D., *Cleveland, Ohio*

THE observations reported in this paper were made in the management of 60 patients, some of whom had been treated with various preparations of protamine-insulin since February 1936. Since August 1936, all patients in this group have received protamine-zinc-insulin. Cases of all degrees of severity have been treated and four children are included in the group. The ages of the patients vary from 8 to 76 years.

It has been felt advisable to hospitalize all patients during the first part of their treatment. The hospital stay averaged 18 days. No patient was confined to bed except for some complication. An attempt was made in each case to maintain physical activity comparable to that of the patient's average day. During the hospital stay, venous blood was taken routinely for determination of the blood sugar at 8 a.m., 12 noon, 4 p.m., and 10 p.m. daily and in some cases at other hours in addition, a modification of the Myers-Bailey method being used. Twenty-four hour specimens of urine were collected in four periods daily, the periods ending before meals and at bedtime. Each specimen was tested for sugar by Benedict's qualitative method and when sugar was present, the 24-hour excretion was calculated in grams, Benedict's quantitative method being used. Qualitative estimation of ketone bodies was done on all urine containing more than 1 per cent glucose.

THE INSULIN

The protamine-zinc-insulin used in this investigation contained 40 units of insulin per cubic centimeter and approximately 0.08 mg. of zinc in combination with protamine in a buffered solution. Since the active material is present in fine particles, careful, gentle mixing is important before the withdrawal of each dose. The use of a cool, dry syringe is advised and it is recommended that subcutaneous injection be done in such a way as to insure a depot of precipitated insulin in the subcutaneous tissues. The material was supplied in 5 c.c. vials, each vial bearing the date after which its stability could not be guaranteed.[†]

THE DIET

We have been accustomed to use a high carbohydrate, relatively low fat diet for some years and this practice has been continued. In our attempt to control diabetes of various degrees of severity with one dose of protamine-zinc-insulin, we have in some cases tended to be less rigid regarding the low

* Received for publication May 3, 1937.

[†] The protamine-zinc-insulin used has been generously supplied through the courtesy of Dr. F. B. Peck and the Eli Lilly Company.

level of fat which is usually maintained in such diets. The number of grams of fat per day in the routine diet was 60. It is our impression that a smooth control is more readily obtained when the carbohydrate content of the diet is not elevated above 200 grams per day. Some patients have received 250 grams of carbohydrate per day and the carbohydrate intake has been 175 grams per day or more in 42 of the patients. The average daily intake in the entire group has been carbohydrate, 182 grams, protein, 66 grams, and fat, 75 grams.

The diet for each individual is calculated on the basis of the basal caloric requirement for ideal weight. In obese individuals, we have not usually found it advisable to use a daily caloric intake below such a figure, as this is usually considerably less than the basal caloric requirement for actual weight and thus produces a daily caloric deficit sufficient to maintain loss in weight where this is required. In most instances, the total caloric intake ranges between the basal caloric requirement for ideal weight and 40 per cent above it.

The diet has been divided routinely into three meals containing 30 per cent, 35 per cent, and 35 per cent respectively of the available glucose for the day. Considerable manipulation of this distribution is advantageous at times. With the use of protamine-zinc-insulin, it has not been found to be of frequent advantage to use one meal containing only 20 per cent of the daily available glucose as was advocated by Hagedorn, et al.,² and Root, Marble, et al.,³ using plain protamine-insulin. In some cases we have divided the daily intake into four meals, giving a small proportion of the food as a luncheon at bedtime. This has the advantage of creating more even intake of food throughout the 24 hours and thus offsets to some degree the tendency to fasting hypoglycemia. In those cases in which there is an undue rise of blood sugar by noon, it is an advantage to deduct the food for the bedtime lunch from the regular breakfast.

DURATION OF ACTIVITY

Estimates of the duration of activity of a single dose of protamine-zinc-insulin in the human have been obtained from four types of observations.

1. The effect on the blood sugar level of a single dose given with one meal after which the patient is required to fast until such time as the blood sugar level tends to rise again after the action of the insulin is diminished. By such a procedure in mild cases, hypoglycemia can be maintained for a period extending to nearly 30 hours.

2. The number of hours during which blood sugar levels in a diabetic can be controlled by a single dose when the patient is receiving regular meals. This type of observation applies obviously to those cases in which the diabetes is of such a degree of severity that the blood sugars are almost but not completely controlled by diet alone.

3 The third type of clinical observation which indicates definitely that the insulin compound acts for more than a day is the commonly observed cumulative effect of daily doses over the first three days of its administration

Figure 1 shows the effect of a single dose of protamine-zinc-insulin given at 7 a m , at which time a breakfast of 45 grams of carbohydrate 14 grams of protein, and 22 grams of fat was given after which the patient had no more food for 30 hours The distinct fall in blood sugar levels is obvious in from three to six hours and subsequently the fall is gradual and consistent The maximum effect is obtained 12 hours after administration Hypoglycemia is maintained in this case to the twenty-seventh hour In several observations of this type, the maximum effect appears in from 15 to 18 hours Larger doses, however, may maintain hypoglycemia for a much longer time, as in Rabinowitch's ⁴ case in which a single dose of

FIG 1

50 units of protamine-zinc-insulin maintained hypoglycemia for more than 36 hours

The second type of observation mentioned is visualized in figure 2 In this patient, the diet which contained C 100, P 50, and F 60, controlled blood sugar levels through the day except for the fasting levels which were 150 to 165 mg per hundred cubic centimeters A single dose of protamine-zinc-insulin was given on the morning of October 28 It will be noted on the chart that the fasting blood sugar levels were normal for two subsequent days, after which they rose to their original levels Another single dose of protamine-zinc-insulin at that time controlled the fasting blood sugar levels for two more days

The cumulative effect of daily doses of protamine-zinc-insulin is observed in nearly every instance in which the use of this material is begun The maximum cumulative effect usually appears to be most marked on the third day and is most obvious in comparing the fasting blood sugar levels

This appears to indicate that the dose given on the first of three days is still active to some degree on the third and also shows clearly why a reduction in dosage, as compared to regular requirements of insulin, usually is necessary

Figure 3 shows the blood sugar levels in a case in which fairly satisfactory control was obtained with three doses per day of regular insulin, the doses being given at 8 a m , 5 p m , and 10 p m . The first day depicted on the chart is a fairly typical representation of the previous control obtained, and it will be seen that the total required daily dose of regular insulin was 67 units . The patient had a mild afebrile infection of one great toe . She had been under control with regular insulin for two weeks prior to the use of protamine-zinc-insulin and had shown no significant alteration

FIG 2

in necessary dosage . On the morning of November 3, 60 units of protamine-zinc-insulin were given in a single dose and this dose was repeated the following day . As will be seen, the fasting blood sugar level on the third day was distinctly lower than were those the first two days and on this day it was necessary to make an addition to the diet because of excessively low blood sugar levels . When the dose of protamine-zinc-insulin was reduced sufficiently to allow fasting levels to rise to the normal range, blood sugar levels during the day were not maintained at normal levels, indicating the necessity for an additional small dose of regular insulin . This patient was subsequently well controlled with a morning dose of protamine-zinc-insulin of 36 units, together with a dose of 6 units of regular insulin at noon

The cumulative effect of a single matutinal dose of protamine-zinc-insulin may be shown by examining the average fasting blood sugar levels in a series of patients during the first few days of control with this insulin as compared with the average fasting blood sugar level preceding its ad-

FIG 3

FIG 4

ministration (Figure 4) Fifteen cases were selected for this purpose. These patients were all under relatively recent control. The period of control with regular insulin in the hospital varied from 5 to 21 days and averaged 10.9 days before the first dose of protamine-zinc-insulin was given. During the period of regular insulin therapy, the diets were in-

creased in some of the cases but were at a fixed level for a period averaging 8.7 days. This dietary level was maintained throughout the period represented in the chart in all but one case in which it was raised because of insulin reactions. It was subsequently maintained at the new level.

The average reduction in total dosage of insulin is shown in the chart. In spite of the reduction in dosage, there was a distinct reduction in fasting blood sugar levels which was most obvious during the first three days. The detached block at the end of the chart indicates the amount of protamine-zinc-insulin necessary for control on the same diets at a period of from two to eight weeks later. As in other cases in the series, the reduction in dosage may fairly be ascribed in part to the fact that the patients had been under control for a short time only before the use of protamine-zinc-insulin. The fact that control was maintained in each instance on a dose suddenly reduced by about 20 per cent cannot, however, be explained on this basis and must be ascribed to the increased efficiency of the new insulin.

NUMBER OF INJECTIONS

Since the duration of activity of each dose of protamine-zinc-insulin is distinctly longer than 24 hours, there seems to be little or no advantage in giving more than one dose per day. A single dose per day usually is sufficient to control fasting blood sugar levels and the degree of depression of these levels apparently marks the limit of increase of the protamine-zinc-insulin dose.

TIME OF INJECTION

Although the duration of the effect of a single dose is longer than 24 hours, its effect is diminished in most instances after 18 hours. This being true, it seems advisable in most cases to give the single daily dose at a period longer than 18 hours prior to the low level of the day which usually is before breakfast regardless of the time of administration of the insulin. For this reason we have usually used the single daily dose before breakfast in each instance. In several cases in which the morning dose was shifted to before the evening meal, a further fall in fasting blood sugar levels was seen without any obvious advantage in control of the blood sugar levels during the day. In a few cases a second daily dose of protamine-zinc-insulin may be used to advantage and, in very severe cases, still better control may be obtained by supplementing one or both doses with regular insulin.

ESTIMATION OF THE DOSAGE

In estimating the dosage of protamine-zinc-insulin, two chief factors must be borne in mind: (1) that the effect is cumulative as shown above, and (2) for this reason the total daily requirement must invariably be less than the regular requirement of insulin. Due to improvement in control the required dosage may subsequently fall considerably. Where poor con-

tiol is present and rapid improvement can be anticipated, this cumulative effect may be dangerous if it is not considered carefully

Figure 5 shows the fasting blood sugar levels in a case in which control was poor while the patient was receiving 60 units of regular insulin per day. When the daily dose of regular insulin was raised to 80 units, the blood sugar levels fell somewhat but were still far above the normal range. Instead of first obtaining good control with regular insulin as we subsequently have found advisable, it was decided in this case to change to protamine-zinc-insulin, arranging a combination of protamine-zinc and regular insulin in such a way as to make the dose approximate 90 to 95 units per day. After the use of protamine-zinc-insulin for three days, the fasting blood

FIG 5

sugar levels had fallen to the normal range. The dosage was not reduced sufficiently at this time and the hypoglycemia which followed is apparent. It is interesting to note that no insulin reactions occurred. This case demonstrates the difficulty involved in estimating the proper dosage where good control is not obtained prior to the change from regular insulin to protamine-zinc-insulin.

When fairly stable control is first obtained with regular insulin, an immediate substitution with protamine-zinc can usually be made. However, we feel that the doses of protamine-zinc-insulin should seldom equal the doses of regular insulin and in cases of moderate severity it has been our practice recently to substitute a single dose of protamine-zinc-insulin of

about 80 per cent of the regular requirement of insulin. In the more severe case, considerable rise in blood sugar levels during the first few days is likely to occur. During this time, glycosuria is present but we have not seen acidosis of consequence during such a transition period. If the rise in blood sugar levels during the first two days of such a transition period tends to be excessive, it may be prevented by the addition of one or two doses of regular insulin which will not usually need to exceed more than 10 per cent of the previous requirement of regular insulin. Within a week, further reduction in insulin dosage is often necessary and in many of our cases even after leaving the hospital, further reduction may be found advisable within a period of two or three weeks.

FIG 6

Figure 6 shows the blood sugar levels during a typical day of moderately good control with three doses of regular insulin, totaling 49 units. This patient was under control with regular insulin for 16 days prior to November 27. On November 27, 80 per cent of this dose, i.e., 40 units of protamine with regular insulin, was given as a single morning dose. The typical rise in blood sugar levels during the day for the first few days is apparent and the gradual fall in fasting blood sugar levels is also demonstrated. Subsequent reduction in dosage is shown and excellent control has followed the use of 33 units per day of protamine-zinc-insulin as compared to a less satisfactory control previously on 49 units per day of regular insulin.

Figures 7 and 8 show control for several days on diminishing doses of regular insulin, together with a smooth transition period and subsequent

FIG 7

FIG 8

excellent control beginning with 80 per cent of the regular requirement of insulin with subsequent reduction in dosage

As indicated above, in mild cases where only the fasting blood sugar level remains high, this can readily be controlled by daily single doses of protamine-zinc-insulin and such control can be accomplished by doses as small as 5 units per day

Even in severe cases, the fasting blood sugar level will be the lowest of the day and, with sufficient dosage, it can be brought within normal range. If it is obvious, however, that the blood sugar levels during the day will not be controlled by such a dose, it will be necessary to add one or two doses of regular insulin. Such a case in which control was difficult is shown in figure 9

FIG 9

The general rules which we follow at present, therefore, in changing from regular to protamine-zinc-insulin may be summarized as follows

The patient is placed on a well regulated diet and good control is obtained with regular insulin. An immediate change is then made with a single morning dose of protamine-zinc-insulin which is approximately 80 per cent of the previous requirement of regular insulin.

If the blood sugar levels during the day are excessively high, about 10 per cent of the previous requirement of regular insulin is added. The dosage of protamine-zinc-insulin is then manipulated in such a way as to

obtain relatively normal fasting levels, changes in dosage not being made oftener than every third day. Subsequently, if morning reactions occur and if the fasting urine is sugar-free or if the fasting blood sugar levels are excessively low for two successive days, a reduction in protamine-zinc-insulin is necessary. If, on the other hand, sugar appears in the morning urine and if the fasting sugar levels remain high for more than two consecutive days, the protamine-zinc-insulin dosage may be increased. Where the fasting blood sugar levels are well regulated, one or two additional doses of regular insulin will be necessary if the blood sugar levels during the day persist at abnormal heights.

REACTIONS

It is a remarkable fact that with the use of protamine and protamine-zinc-insulin, the blood sugar level may reach 40 mg per hundred cubic centimeters or below without reactions. Reactions do occur, however, but for the most part they tend to be mild and gradual in their onset, thus allowing more time for treatment. Because of the gradual onset of such reactions, it is more difficult for the patient to detect an approaching reaction. Because of the prolonged effect of protamine-zinc-insulin, the reactions themselves are likely to be prolonged and to recur after treatment. Considerable hypoglycemia may occur without pronounced symptoms. It becomes more necessary than ever, therefore, to elicit any symptoms or signs which may be evidences of hypoglycemia. This is especially true in elderly individuals or in those with arteriosclerosis, especially arteriosclerotic heart disease. Fatigue, tingling, slight disturbance of memory, irritability, slight difficulty in speech, mild nausea, or headache should be suspected as possible symptoms of hypoglycemia. I have seen three severe reactions. One was associated with a convulsion, and this occurred in a child whose symptoms of hypoglycemia were present in this instance for nearly 12 hours. One occurred in a patient with severe diabetes which required 70 units of insulin per day. This patient lay down to rest after breakfast and was unconscious until he was awakened and found to be in obvious hypoglycemic shock at 5 a m the following morning. (He went to work as usual that day). The third patient took 50 units of insulin instead of 25 as ordered.

In the treatment of protamine-zinc-insulin reaction, it is advisable to use small doses of glucose or milk, to be prepared to repeat the treatment if necessary, and to avoid the use of excessively large amounts of sugar at one time.

REDUCTION IN DOSAGE AND IN NUMBER OF INJECTIONS

In 17 patients in this group, previous control had been good and had been maintained at a relatively stationary level for more than six months preceding the use of protamine-zinc-insulin. The average daily requirement of regular insulin had been 34.3 units while that of protamine-zinc-insulin was 22.0 units. In the older and better controlled cases, the reduction in

dosage is less than in the recently controlled cases. Of the entire group, the daily dose dropped from an average of 42.3 units of regular insulin to 25.4 units of protamine-zinc plus regular insulin.

Accessory regular insulin was necessary in 17 cases. The average number of daily injections necessary in the whole group was 2.8 of regular insulin as compared with 1.3 of protamine-zinc. This difference appears to be increasing with experience since, in the last 28 patients treated, the use of accessory regular insulin has been found necessary in only two instances. The average daily number of injections in this smaller group was 3.0 of regular insulin and 1.1 of protamine-zinc-insulin.

CONTRAINDICATIONS

The usually recognized contraindications are acidosis, infections, and pre- and postoperative care. Attempts are being made to determine the usefulness of protamine-zinc-insulin in these conditions but experience is not sufficient to warrant comments.

COMMENTS

Since the appearance of Hagedorn's paper in January 1936² his original claims that it had a prolonged action, gave better control in most cases, a tendency to less frequent insulin reactions with a diminishing number of injections and a reduction in actual dosage have largely been corroborated by other investigators.^{3, 4, 5, 6} More recently, the addition of zinc to protamine-insulin has received considerable attention and it appears that the use of protamine-zinc-insulin has superseded that of plain protamine-insulin.

Although the advantages of protamine-zinc-insulin outweigh its disadvantages, the latter have not received sufficient emphasis. Better control can be secured with it in many cases but regulation, especially in the severe cases, is more difficult and will require a more intelligent grasp of the problem by the physician than has been necessary previously.

The comparative effectiveness of protamine-zinc-insulin should not be judged by blood sugar levels alone since, in some instances, it can be shown that even though the blood sugar levels fasting and four hours after meals are in good control, there may be more glycosuria than when the same levels are maintained with regular insulin. This appears to be due to the absence of the timely effect of insulin seen where regular insulin acts approximately synchronously with food absorption, as compared to the absence of this effect with protamine-zinc-insulin. It is remarkable that such increased glycosuria occurs infrequently.

Hospitalization for control is more important when protamine-zinc-insulin is used and usually will be more prolonged. Although reactions are less frequent, if they do occur, they are likely to be more difficult to detect and more prolonged.

In some of my cases reactions have occurred because the patient, having

taken a relatively large dose of protamine-zinc-insulin in the morning, has been unable to take all the food prescribed or has vomited part of the noon or evening meal. With regular insulin one would have the opportunity of reducing the noon or evening dose but this cannot be done with protamine-zinc-insulin. What effect this will have on the patient with arteriosclerosis remains to be seen. Some of the early disadvantages, such as instability of the solutions and the necessity of mixing them, have already been overcome.

Against these disadvantages we have more stable control, fewer injections, and lower dosage with protamine-zinc-insulin. It is hoped that, as a result of the better control, there will be a diminution in the incidence of hyperlipemia, liver disease, and degenerative disorders, especially arteriosclerosis. In these respects, the responsibility of the profession has increased.

SUMMARY

Protamine-zinc-insulin in common dosage appears to be active for 50 to 65 hours after injection. Its maximum effect is usually maintained between 12 and 18 hours. The prolonged effect of single daily doses makes it unnecessary usually to use more than one dose daily. The cumulative action increases to the third day or longer and reduces the requirement of insulin to less than 75 per cent of the dose of regular insulin in most cases. The number of injections, dosage, and the frequency of reactions are all reduced by its use. The most obvious advantage is in reduction in number of doses necessary. In all except two cases in which we have used it thus far, control has been as good or better than with regular insulin. It should be pointed out, however, that this improved control represents in some cases the combined use of protamine-zinc-insulin and of regular insulin. A normal fasting blood sugar level marks the limit of increase in protamine-zinc-insulin dosage. If, when this limit is reached, the blood sugar levels during the day remain high, one or more accessory doses of regular insulin are required for control. In some mild cases, a dose of protamine-zinc-insulin every second or third day may be sufficient to control fasting sugar levels.

THE ASSOCIATION OF SCIATIC NEURITIS WITH LIVER DISEASE *

By S S LICHTMAN, M D, *New York, N Y*

PERIPHERAL neuritis occurs commonly in metabolic disorders such as gout and diabetes. In severe anemia, renal and hepatic diseases, on the other hand, the central nervous system is more frequently involved. Lenticular degeneration has been described in association with cirrhosis of the liver¹. Involvement of the peripheral nerves may also complicate liver disease. Polyneuritis has been ascribed to jaundice independently of a basic vitamin deficiency or alcohol abuse,² and also it has been thought due to the severe liver damage of biliary obstruction³. Neuritis has been noted in subjects with pigment cirrhosis, particularly in those with involvement of both the pancreas and liver⁴. Endogenous toxic substances resulting from hepatic insufficiency have been held responsible for causation of the neuritis.

This report of five cases indicates that the symptoms of sciatic neuritis in some instances may be a precursor of hepatic insufficiency. Though an analgesic effect of hepatitis and jaundice upon sciatic pain has been noted, the possible relationship between the jaundice and the antecedent sciatic pain has escaped notice. Such a relationship may be important, for the development of jaundice, sometimes fatal, has recently been ascribed to the use of cinchophen prescribed for its analgesic effect.

The following clinical observations suggest that sciatic neuritis may be an early manifestation of a disease process which may lead to liver disease and hepatic insufficiency. It is suggested that endogenous or exogenous toxic agents may affect peripheral nerves before their hepatic effects become manifest clinically.

CASE REPORTS

Case 1 B M, 48 years old, complained of bloating, belching and intolerance to fatty and fried foods of many years duration. For 18 months he had suffered a sensation of epigastric discomfort after meals. For six months he had suffered progressively more severe, cramp-like pains shooting down the posterior aspect of his left buttock, thigh, and calf. At times, only a feeling of numbness or discomfort existed. A month before admission to the hospital, the patient developed jaundice, darkly colored urine and clay-colored stools. He complained of generalized itching. His appetite failed him. He lost 10 pounds in weight. The only medication ingested by the patient throughout the course of his illness before admission to the hospital was ten grains of aspirin. With the onset of jaundice the pain in the left lower extremity became milder but did not disappear.

An enlarged, smooth, firm liver and an enlarged spleen were found on examination of the abdomen. Neurological examination revealed negative Patrick

From the Medical Division, Service of Dr George Baehr, The Mount Sinai Hospital, New York

and Lasegue signs in the extremity affected with pain. The ankle jerk was present. The blood Wassermann reaction was negative.

Ascites and dependent edema developed. The patient lapsed into stupor and died despite intensive intravenous glucose therapy.

Necropsy confirmed the clinical diagnosis of subacute liver atrophy. The gall-bladder was normal in appearance and contained no stones. There was little evidence of hepatic regeneration microscopically. The pathological picture was also interpreted as a form of toxic cirrhosis. Unfortunately material was not obtained from the sciatic nerve in this case, or in case 4, for histological examination.

Case 2 S. M., aged 52 years, had received anti-luetic therapy. The last course of salvarsan had been administered five years before the hospital admission for diagnosis as to the cause of jaundice. For three weeks before the development of jaundice, the patient had suffered from severe pain in the posterior aspect of the right knee and thigh. Cinchophen had not been ingested.

The liver was enlarged and the spleen was not palpable. On neurological examination all reflexes were normal. The Kahn test was 3 plus.

The jaundice disappeared promptly. The sciatic pain subsided with the onset of the jaundice. The patient was ambulatory during his illness. In the four years since this illness, the patient has suffered no recurrence of sciatica.

The jaundice was classified as a so-called "catarrhal jaundice." In view of the fact that five years had elapsed since the administration of salvarsan, arsenic from this source was not considered in the etiology of the jaundice or sciatic neuritis.

Case 3 W. M., a physician, aged 45 years, had taken novatophan 18 years previously for severe sciatica. He had recovered from an attack of paratyphoid fever the year before. Splenic enlargement had been first noted 17 years ago, and liver enlargement had been known to exist for 14 years. For two years, left-sided sciatica had been present intermittently. Cinchophen had not been taken in recent years. For two weeks he had noted nausea and fever, and following this jaundice became evident. The sciatic pain subsided.

The liver and spleen were enlarged, and the laboratory tests indicated severe liver damage.

The patient ran a fever at the outset. Generalized itching was pronounced at times. After a protracted course, the jaundice subsided. The sciatic pain recurred after the acute phases of the illness had passed. It was believed that the patient has recovered from an attack of acute hepatitis superimposed upon an old toxic cirrhosis.

Case 4 R. B., aged 57 years, was admitted with a history of pain down the left thigh and leg of sudden onset and of eight weeks duration. After four weeks of pain of increasing severity, the patient had sought medical relief. She had been given six subcutaneous injections of Aolan, a milk preparation, and one intravenous injection of sodium iodide, without relief from pain. A single injection of 5 grains of cinchophen was then administered by a physician. One week later she developed icterus, anorexia, and epigastric distress. The stools became light in color. The sciatic pain definitely subsided with the onset of jaundice.

The liver was found enlarged, the spleen was not palpable. The Patrick and Lasegue signs were positive in the left lower extremity. The knee and ankle jerks were livelier on the right side than on the left.

The liver diminished in size as the illness progressed. Ascites and generalized edema developed and came set in despite intensive intravenous glucose therapy.

The necropsy demonstrated the presence of subacute liver atrophy and subacute pancreatitis.

Case 5 A male, aged 31 years, had suffered an attack of lumbago four years previously. Recently excruciating pain developed in the posterior aspect of his right

thigh and leg. The Lasague and Patrick signs were positive. The condition was diagnosed as acute sciatic neuritis.

The icterus index of the blood was 15 and the bilirubin content 0.6 mg per 100 c.c. (slightly elevated above normal). Ten days later these figures were still elevated. After a fortnight, the icterus index and the bilirubin content of the blood decreased to 8 and to 0.3 mg per 100 c.c. respectively (normal values). The blood cholesterol was 250 and later 235 mg per 100 c.c. The ester partition was normal. The urobilin content of a 24 hour specimen of urine was normal. Tyrosine⁸ was not demonstrable in the urine. The galactose tolerance test showed a normal result. The cinchophen oxidation test⁹ indicated moderate liver cell function impairment. On successive tests, 33.5, 33.0, 31.0 and finally 13.5 per cent of the test dose of 0.45 gram of cinchophen were excreted as oxy-cinchophen. Normal subjects excrete less than 21 per cent of this partial oxidation product in the urine after the test dose. The decrease in the latent jaundice, and in the oxy-cinchophen excretion occurred simultaneously with the subsidence of the pain. The patient was observed over a period of six weeks.

COMMENT

Liver function has rarely been studied in patients with sciatic neuritis. The levulose tolerance test was applied by Miller⁶ to 18 cases of sciatica with evidence of diminished tolerance in five. Eppinger⁷ noted liver function disturbance in five cases of polyneuritis and implicated a hepatic factor even in subjects with definite histories of lead and alcohol poisoning. I observed a marked spontaneous phenoluria or cresoluria in the urine of a female subject suffering from severe sciatic neuritis some years ago while studying tyrosinuria by means of the tyrosinase reaction. (The phenols and polyphenols give a pink reaction with this ferment, while tyrosine produces melanin, a brownish black, or violaceous pigment, specifically.) In the subject with sciatic neuritis reported above (case 5) the icterus index and the quantitative Van den Bergh reaction demonstrated a latent icterus. This subsided with the pain as did the liver function impairment recorded by the cinchophen oxidation test of liver cell function. Thus there is evidence that sciatic neuritis may be accompanied by subclinical hepatic damage.

An analgesic effect attributed to the jaundice was noted in some instances. The relief from pain was greater than could be expected from confinement to bed alone. The pain was noted to recur in one instance as recovery from liver injury took place (case 3). The possible analgesic influence of retained bile salts in jaundice was considered⁴ and the analgesic properties of bile salts were therefore tested experimentally. When introduced into the spinal canal of cats, an analgesic effect was not noted¹⁰. It is suggested that associated disturbances in mineral and water metabolism observed in acute liver degeneration may possibly contribute to the analgesia since some synthetic analgesics also alter water and electrolyte relationships of cells.

Careful interrogation has eliminated the possibility of cinchophen in any form in three of the cases of sciatica complicated by jaundice. In case 4 a single dose of cinchophen (5 grains) had been injected intravenously. In case 3 the patient, a physician, had taken novatophan, 18 years previously, for an attack of sciatica. For his recent recurrent sciatic pain this drug

was not used. In case 1 the only medication taken over a period of six months was ten grains of acetylsalicylic acid, despite excruciating sciatic pain. I doubt whether the ingestion of a single or a few doses of cinchophen in these two cases played any rôle in the causation of jaundice. The administration of single doses of this drug to patients with frank liver damage appears to have no ill effect.⁹ The possibility that liver injury may result from an idiosyncrasy to this drug in certain individuals with or without latent liver insufficiency cannot however be dismissed, but is unlikely in these two instances.

In the cases reported there was no history of alcohol abuse, or lead poisoning to account for the sciatic neuritis. No other nerves were involved. There was no clinical ground for suspecting a vitamin B₁ deficiency.

SUMMARY

Five cases are reported in which the symptoms of sciatic neuritis preceded the onset of clinical evidence of liver damage and jaundice. In three instances the jaundice and liver disease occurred in persons who had not ingested cinchophen in any form.

These observations suggest that endogenous toxic substances, responsible for the peripheral neuritis involving the sciatic nerve, may also be responsible for liver injury.

THE RESPONSE TO THE FEEDING OF CEVITAMIC ACID IN NORMAL AND DEFICIENT SUBJECTS AS MEASURED BY A VITAMIN C EXCRETORY TEST*

By ELAINE P RALLI, F A C P, and GERALD J FRIEDMAN,
New York, N Y

THE criterion for the diagnosis of scurvy had been, until recently, the appearance of the symptoms of scurvy. As a result of the experimental work in vitamin C, three new diagnostic procedures have now come into use: the capillary resistance test, the concentration of vitamin C in the blood and the urinary excretion of vitamin C^{1, 2, 3, 4, 5}. There is still some controversy as to the value of capillary resistance tests as an index of vitamin C deficiency. We have studied the capillary resistance of 25 young normal adults by the Dalldorf method⁵ and found no definite relation between vitamin C excretion, capillary resistance and diet. In this respect our findings agree with those of Anderson, Hawley and Stephens⁶. It is our impression that capillary resistance is influenced by several factors and although it is usually low in patients with scurvy, it is not as reliable an index of the degree of vitamin C deficiency as is the excretion of vitamin C or the blood vitamin C.

In this study the vitamin C excretory test, described in a preliminary report,⁷ was used not only to verify the diagnosis of scurvy and vitamin C subnutrition, but to study the response of such subjects to vitamin C therapy.

Procedure. Three groups were studied: a normal group of 12 young adults whose diet was adequate in vitamin C, a group of 3 normal subjects with no evidence of scurvy but whose diets were low in vitamin C and a third group of 22 patients with clinical evidence of scurvy.

The three hour excretion of vitamin C following the intravenous test dose of 100 mg of cevitic acid was determined in all three groups. In the normal and subnutrition groups the excretion of vitamin C was also determined for the total 24 hours. Following this, vitamin C as cevitic acid (Meck & Co) was fed to nine of the normal subjects, to the three subnutrition subjects and to all of the patients with scurvy.

In addition, to ascertain whether there was an advantage in using a larger test dose than the one originally advised (100 mg of cevitic acid), a group of normal and of scorbutic subjects were given an intravenous injection of 100 mg of cevitic acid and after an interval of two days an injection of 500 mg.

1 *In the Normal Subjects and in the Subjects on Diets Low in Vitamin C.* During the experimental period the subjects remained on their regular

* Received for publication July 30, 1937.

diets, being careful to avoid any change in the intake of food high in the vitamin. The urines were collected as follows. The subject voided one to one and a half hours after breakfast. This specimen was discarded. The urine was then collected for the next three hour period and the vitamin C excretion determined. The urine was also collected for the following 21 hours. The next day, after voiding, the subject was given intravenously 100 mg of cevitic acid (Merck & Co.) and the urines were collected in the same way as before. Vitamin C feeding was then begun as cevitic acid 50 to 100 mg daily and the tests were repeated at intervals.

2 *In patients with scurvy* the same procedure was followed as in the normal subjects, with this difference that in the severe cases the cevitic acid was at first given intravenously and then in larger daily doses. When given by mouth, the cevitic acid was fed at 12 noon and 4 p.m. Cases 22 and 28 had received some orange juice prior to our original excretory determinations.

3 *Comparison of the 100 mg and 500 mg Test Doses on the per cent of the Vitamin Excreted in Three Hours*. In ten normal subjects intravenous test doses of both 100 and 500 mg of cevitic acid were given. An interval of two days elapsed between these two test doses, the 100 mg dose was given first. The urines were collected in the usual manner. This procedure was also carried out on eight patients with scurvy. In this study the urines were not collected for the 21 hours following the three hour test period.

4 *Method of Estimating Vitamin C in Urine and Blood*. Vitamin C was determined by titration against a standardized solution of 2,6-dichlorophenolindophenol by the method of Buch, Harris, and Ray.⁸ All necessary precautions were taken to insure against loss of the vitamin. The urines were acidified to 10 per cent of their volumes with glacial acetic acid. The three hour specimens were titrated immediately. Of the 21 hour specimens, those voided before supper were done immediately and the remaining specimens were collected in dark bottles in which there was a given amount of acetic acid and these were kept in the ice box. We have, as many other observers, studied the rate of destruction of the vitamin in urine and found that in acidified urine, kept in the cold, there is very little loss within 12 to 16 hours.⁹ It is also important that the urine in the bladder should be acid especially in patients with a low excretion of the vitamin.¹⁰ Where there was a tendency for the subject to excrete an alkaline urine, small doses of ammonium chloride were given. This was necessary in four cases.

Blood vitamin C was determined on 15 of the scurvy patients and on nine of the normals by the Farmer and Abt method.⁴

RESULTS

1 *Normals*. Table 1 gives the age, weight, height and capillary resistance of the normal subjects. The three hour excretion (Table 3) of vita-

min C in the normal subjects on diet alone varied from 4.5 to 25 mg, the average being 12 mg. The 21 hour excretion varied from 30 to 180 mg with an average of 67 mg. Following the intravenous injection of 100 mg of cevitamic acid the three hour excretion rose in all the normal subjects, the total excretion varying from 24 to 81.8 mg with an average excretion of 47 mg. The 21 hour excretion rose in four cases and fell or remained approximately the same in the rest of the group. The average 21 hour excretion was 67 mg. The intravenous test dose done after the feeding of 400 mg of cevitamic acid to nine of this group was followed by an increased excretion within three hours in five of the nine subjects. The average excretion in three hours for these nine subjects rose to 64 mg, and in the following 21 hours rose to 88 mg, thus raising the average 24 hours excretion to 152 mg. Continued feeding of cevitamic acid in six subjects further increased the three hour excretion after the intravenous test dose. The subject in whom no further increase was effected had originally excreted 81.8 mg of the 100 mg injected. Three of the subjects, after continued feeding of cevitamic acid, excreted more than 100 mg of vitamin C in the three hours after the test dose. Part of this was of course derived from the tissue stores and suggests a state of complete saturation.

2. *Subjects on Low Vitamin C Diets (Table 4)* On diet alone these subjects excreted an average of 1.9 mg in three hours and 10.2 mg in 21 hours, a total of 12 mg for 24 hours. The test dose caused a rise in the three hour excretion, but this was far below that seen in the normal subjects, the average being 10.4 mg. The following 21 hour excretion was not raised but actually was lower. After feeding 1000 mg of cevitamic acid, all three

* Second study after an interval of 3 months

† Amount of cevitic acid fed at the time of this test was 650 mg

subjects excreted more than 36 mg of the injected vitamin, the average being 44 mg. The 21 hour excretion rose, but was not as high as the average excretion in the normals on diet alone. Continued feeding of cevitic acid caused an increase in the three hour excretion following the test dose and the 21 hour excretion rose in two of the subjects. Case 14 was studied a second time after an interval of three months, during which time he had received no cevitic acid. The excretory test was again low, 2.8

mg After feeding 650 mg of cevitamic acid, the excretion after the test dose rose to 17 mg and after feeding 1500 mg, 38.5 mg were excreted

3 *Patients with Scurvy* (A) *Symptoms* Table 2 summarizes the symptoms and signs of vitamin C deficiency observed in the 22 cases studied. Only six cases were uncomplicated. Malnutrition was profound in two cases. Arteriosclerosis in varying degrees was present in four cases. Symptoms referable to the gums were found in 16 cases. These varied considerably, but definite piling up of the gums with retraction from the teeth was present in 13 cases. Hemorrhage or petechiae or both were found in 15 patients. The capillary resistance done in 13 cases was low in nine. The blood vitamin C, done in 15 cases, was below 0.55 mg in twelve. In one case, number 28, the patient had had orange juice for one week before the study and the blood vitamin C was normal.

(B) *Excretion in Patients with Scurvy* (Table 5) These patients were on the wards of the Third (New York University) Medical Division, Bellevue Hospital. Cases 22, 28 and 41 were studied in the Metabolism Clinic of the College of Medicine Clinic, New York University. Case 26 was studied twice, once in the clinic and later in the hospital. Prior to the administration of vitamin C, the average three hour excretion in the scurvy patients was 1.4 mg. In some cases no vitamin C was titratable in the urine, in four cases it was less than 1 mg. The 21 hour excretion averaged 6 mg. After the 100 mg test dose of cevitamic acid, the average three hour excretion was 2.5 mg. The 21 hour rose to an average of 10 mg. In cases 20, 21, 29, 30, 31, 39 and 41 cevitamic acid was given intravenously until clinical improvement was noted and then by mouth. The tests were repeated at frequent intervals after the feeding of the vitamin and in six cases (23, 26, 27, 31, 32, and 36), the excretion was followed daily during the patient's stay in the hospital. The other patients were followed at weekly or semi-weekly intervals. In five cases (33, 34, 35, 37 and 38) although cevitamic acid was administered, excretory tests were done only after the test dose. In table 5 the excretory tests following the administration of cevitamic acid are reported. As it would require too much space to report every case in detail, this table summarizes the results at intervals during the studies.¹ In those cases where the excretion was determined daily, it was found that the excretion remained low for from 4 to 12 days and then approached the normal. The amount of cevitamic acid required to bring the excretion to the normal level depended on the duration of the deficient diet and the presence of complicating conditions.

4 *Comparison of 100 mg and 500 mg in Test Doses of Cevitamic Acid on the Three Hour Excretory Test* Ten of the normal subjects (1, 3, 4, 5, 6, 7, 8, 10, 12, 13 and 15) were given intravenous test doses of 100 mg of cevitamic acid and two days later 500 mg. These tests were carried out three months after the original studies were completed. The normals excreted an average of 53.8 per cent in three hours after the 100 mg test dose and 55.8 per cent after the 500 mg test dose. Undoubtedly the higher

excretion within three hours represents a higher dietary intake of vitamin C. These normal subjects had become vitamin C conscious as a result of these studies and almost all had increased their daily intake. Eight patients with clinical signs of scurvy were similarly tested. The average three hour excretion after the 100 mg dose was 1.6 per cent, after 500 mg, 7 per cent.

The results on the normal subjects show that there is no particular advantage in using the larger test dose of cevitamic acid. In the patients with scurvy, apparently the per cent excretion is somewhat higher following the larger dose. If such a dose were to be used, it would merely require establishing the limits of the three hour excretion. We feel, however, that as

the smaller test dose gives consistent and accurate results, it is preferable to a larger one because in following the excretory response to vitamin C therapy, there is less chance of saturating the patient when the smaller dose is used

DISCUSSION

From these studies it is obvious that normal young adults on a presumably normal diet will excrete varying amounts of vitamin C daily. The question arises as to what constitutes a normal excretion. From our results and the results of other investigators¹⁻³ there is apparently a rather wide range of excretion in the normal which is naturally influenced by diet. In view of the difficulties of collecting 24 hour urine specimens and of protecting against loss of the vitamin in urines collected over a long period of time, we have attempted to evaluate the significance of the excretion for a three hour period after an intravenous test dose of cevitic acid. The three hour ex-

FIG 1 Case 39 The three hour excretion tests before and after the administration of cevitamic acid

cretion on diet alone may be fairly low in normal individuals. If, however, one studies the three hour excretion following an intravenous test dose of 100 mg of cevitamic acid, the difference in excretion between normal subjects, scorbutic subjects and subjects on a low vitamin C diet is quite definite. Of the 12 normal subjects studied prior to feeding any additional vitamin C, 11 excreted more than 32 per cent of the injected vitamin in three hours. Of the three subnutrition subjects all excreted less than 15 per cent in three hours and in the subjects with scurvy, excluding cases 22 and 28 who had been receiving orange juice prior to the original test, all excreted less than 5 per cent in three hours. These results were consistent with the 24 hour excretion. It seems reasonable, therefore, to suggest that the excretion of vitamin C following an intravenous test dose of 100 mg can serve as an index of whether or not the subject is deficient in vitamin C.

The results of feeding vitamin C to these three groups of patients bring out the fact that the normal subjects excreting less than 80 per cent of the

injected vitamin in three hours can be stimulated to excrete larger amounts following the feeding of vitamin C. One may infer that when more than 70 per cent of the injected vitamin is excreted in three hours, the tissues of the individual are well saturated with the vitamin. This does not mean, however, that complete saturation of the tissues is necessary in an individual in order to have a normal state of vitamin C nutrition.

The subjects on the low vitamin C diets responded very promptly to the feeding of vitamin C and their three hour excretion reached the normal level after the feeding of 1000 mg of cevitic acid. In this respect they show again the difference between subnutrition and absolute deficiency of vitamin C. The scorbutic patients required much larger doses before their three hour excretion test fell within a normal range. In fact in some instances this did not occur during the period of these observations.

The diets of the subnutrition cases are the ones of most interest in the field of nutrition. The three subjects studied were medical students and their diets were low in fresh fruit and in uncooked vegetables. Practically none of these men took any oranges and only occasionally an apple. Their response to the feeding of cevitic acid suggests that their tissue reserves of the vitamin were low, but apparently had not reached the stage where any demonstrable clinical or pathological effect could be found. The capillary resistance in two of these subjects was 20 cm and was 40 cm in the third subject. It is quite likely that pathological changes in the tissues as a result of vitamin C deficiency do not occur until an absolute state of deficiency has existed for some time. Youmans and his associates¹¹ found that of 15 subjects whose diets were inadequate in vitamin C, 12 excreted less than 20 mg of the vitamin in the urine daily. The 24 hour excretions in our subnutrition group substantiate these findings.

Of the 22 cases showing symptoms of scurvy, only six cases were uncomplicated by other diseases. This brings up the fact that vitamin C deficiency is probably seldom uncomplicated and that other pathological states may increase the vitamin C requirement of the individual. Administration of cevitic acid improved the clinical symptoms in all cases, in several cases this improvement was apparent before the excretory test had reached the normal level.

SUMMARY

- 1 The three hour urinary excretion of vitamin C before and after an intravenous test dose of 100 mg of cevitic acid was studied in a group of 12 normal adults, 3 normal individuals on diets low in vitamin C and 22 cases of scurvy.

- 2 The three and 21 hour excretion was studied in the same group after an intravenous test dose of 100 mg of cevitic acid and the intravenous test dose was repeated in all three groups following the feeding of cevitic acid.

3 Following the intravenous test dose the 12 normal subjects excreted an average of more than 40 per cent of the injected vitamin within three hours. The extremes were 24 to 82 mg. The three subnutrition cases excreted 5 to 14 mg. The cases with scurvy excreted from 0 to 5 mg.

4 Following the feeding of 1000 mg. of cevitamic acid to the subnutrition subjects, the three hour excretion rose to the normal level after the test dose. In order to increase the urinary excretion to the normal level in the patients with scurvy much larger amounts of the vitamin had to be fed. In the normal group the feeding of cevitamic acid in small doses increased the vitamin C excretion above the original level.

5 Excretion tests were also done following an intravenous test dose of 500 mg. of cevitamic acid in normal and scorbutic subjects. The normals excreted an average of 55.8 per cent, the scorbutic patients an average of 7 per cent of the injected vitamin.

6 As a result of these observations it is suggested that the urinary excretion of vitamin C following an intravenous test dose of 100 mg. of cevitamic acid will serve as an index of vitamin C deficiency or subnutrition and as a guide to show the degree of saturation of the tissues following the feeding of cevitamic acid.

PEPTIC ULCER THE EFFECT OF THE ADMINISTRATION OF BILE ON THE BEHAVIOR OF THE DISEASE ^

By EDWARD S EMERY, JR, M D, and MAURICE A SCHNITKER, M D,
Boston, Massachusetts

Two reasons prompted us to administer bile to patients with peptic ulcer the evidence from experiments with animals that ulceration of the stomach or duodenum may follow the diversion of bile from the duodenum, and certain other evidence which suggests that the disease may result from some type of deficiency

Numerous studies have been reported in which ulceration has developed after interference with the normal secretions in the duodenum A review of the literature on this subject has been published by us in two previous articles ^{1, 2} and will not be repeated here Briefly, the various experimental methods that have been most successful in producing peptic ulcerations in animals, usually dogs, have involved side-tracking or shutting off the flow of bile or pancreatic juice to the duodenum, or damaging the liver, as by chemical poisons, cinchophen, etc These studies may be divided into three groups

(1) Experiments which have severed the duodenum from the stomach, and in this way prevented a normal mixing of hydrochloric acid with the duodenal secretions, succus entericus, bile and pancreatic juice

(2) Experiments which have diverted only one of these three secretions

(3) Experiments which have caused damage to the liver

In addition, there have been observations, both in animals and in man, of spontaneous ulceration in association with a diseased liver

The experimental work included under groups 1 and 2 was inspired by the conception that ulcer might be the result of a defect in the process of neutralization of the gastric juice by regurgitated alkaline duodenal contents The results of this work support the contention that unneutralized hydrochloric acid can damage the mucous membrane However, it is difficult to apply the interpretation of these results to an explanation of the cause of ulcer in man One cannot consider the damaging effect of the acid without considering the resistance of the mucous membrane to that effect Indeed, most investigators have felt that trauma and the resistance of the mucous membrane are important factors in determining whether these experimental ulcers develop As these complex experiments were carried on, it was found that tying off either the biliary or pancreatic ducts might be followed by the development of an ulcer A question then naturally arose as to which was

* Received for publication May 21, 1937

From The Medical Clinic of the Peter Bent Brigham Hospital

the more important of the two. On this question various observers have disagreed. Ivy and Fauley,³ Elman and Hartman⁴ have found a high incidence of ulcer formation in animals following interference with the normal flow of pancreatic juice into the duodenum. Conversely, Kapsinow,⁵ Weiss and Hubster,⁶ Berg and Jobling,⁷ Bollman and Mann,⁸ and others have found a higher percentage of ulcer formation following interference with the normal flow of bile. Berg and Zucker,⁹ and Berg¹⁰ comparing the frequency with which ulcers followed the diversion of bile or pancreatic juice found the greater incidence of ulcer formation after the exclusion of bile.

The evidence at present suggests that the loss of bile is the more important of the two. Strengthening this idea is the recent work reported by Blanck¹¹ in which ulcers developed in five of eight dogs after the complete external drainage of bile. Moreover, he claims to have prevented the development of ulcerous lesions in three other dogs similarly treated by refeeding the bile drained off. It is unfortunate that after the lesions developed, he did not attempt to bring about their healing by the administration of bile. It is evident that the lack of either bile or pancreatic juice in the duodenum, or the loss of these substances will frequently result in the formation of an ulcer in experimental animals. But, the explanation that these lesions are the result of an inadequate neutralization of the gastric juice seems to rest on insecure evidence. Certainly, this explanation cannot easily be applied to the behavior of ulcer in man.

Our present knowledge about peptic ulcer logically divides our theories on its etiology into two groups: (1) that peptic ulcer is due to the destructive effect of hydrochloric acid on a normal mucous membrane, or (2) that the disease results from a local decreased resistance of the tissues to peptic activity of the gastric juice. There is undoubted evidence, both experimental and clinical, that peptic activity plays a role in the development of ulcerous lesions (Mann and Williamson,¹² Matthews and Dragstedt,¹³ Lindau,¹⁴ and others). However, there is no evidence that it is the sole cause of the lesion. If the ulcer is associated with the hydrochloric acid, changes in the activity of the ulcer must be associated with a change either in the acid, or in the resistance of the tissues to the damaging or corrosive effect of that acid. There is no evidence that the quality of the human gastric juice varies with a change in the state of the ulcer which would seem inevitable if the destructive effect of the juice were the important factor in the development of the lesion. Recently, Schnitker and Evans¹⁵ have reported that there is no change in the quality or quantity of human gastric juice from the period of a preulcerous state to the time when an active lesion could be demonstrated. Moreover, there are a sufficient number of cases of ulcer with low acid values to make it seem probable that peptic ulcer in man depends upon something other than, or in addition to, the destructive effect of the hydrochloric acid. The progressive susceptibility of the lower intestine to the corrosive effect of the gastric juice suggests the importance of

the normal resistance of the tissues to this damaging influence. Also, it is difficult to believe that the factor of safety in the mechanism for neutralization of the hydrochloric acid is so slight that a diversion of either one of the alkaline juices is sufficient to leave the duodenal mucous membrane unprotected.

The other theories, such as the neurogenic, vascular, and infectious fall into the second group, implying a decreased tissue resistance. These theories are based more upon clinical observation than upon experimental work. The experimental ulcers which most resemble those found in man have been produced only by technics similar to or related to the Mann-Williamson operation. This does not lend support to the neurogenic, vascular, or infectious theories.

That a deficiency of some kind may be the cause of ulcer is a possibility which has received little attention, although there is much in the behavior of the disease to make tenable such an hypothesis. The clinical behavior of the disease is comparable in many ways to that of pernicious anemia, which is also chronic, passing through alternating cycles of activity and quiescence, and being influenced by emotion, fatigue, and infection, similarly to ulcer. All the experimental work based on the operative principle stressed by Mann and Williamson, of necessity interferes with the normal physiology of the gastrointestinal tract. There has not been excluded the possibility that the formation of ulcer may depend upon a disturbance in digestion which results in a deficiency. The fact that a diversion of any of the secretions found in the duodenum will produce an ulcer, favors the idea that a disturbance in digestion is the cause of the disorder as much as, if not more, than it favors the theory of failure in neutralization of the gastric juice as a causative factor. Supporting this idea of "deficiency" are the studies carried out by McClure and Huntsinger¹⁶ in which they found that in 8 of 12 patients with symptoms of an uncomplicated duodenal ulcer, the biliary fraction was "decidedly abnormal," particularly with respect to the bile acids.

In summary, therefore, we have been led to administer bile to patients with peptic ulcer because of the reports in the literature of instances in which lesions of the gastric or duodenal mucosa have been associated both in animals and in man with interferences with the normal flow of bile into the duodenum, because the absence of bile seems to be more important than loss of pancreatic juice in the formation of ulcer, because peptic ulcer may be considered a type of "deficiency" disorder in which a loss of the protective mechanism of the duodenal mucosa allows ulcers to develop, and, because studies of the bile have shown an abnormality in cases of duodenal ulcer.

The administration of bile to patients with gastric complaints, or even peptic ulcer, is not new, although at the present time there is much more experimental and clinical data to suggest and warrant its use than was available to the previous experimenters. About 1913, Palfrey¹⁷ in this country, and Glacssner¹⁸ in Germany discussed the treatment of peptic

ulcer with the use of bile. Both writers reported symptomatic improvement in their cases. Jarno¹⁹ in 1926 and Thom²⁰ in 1932 have also discussed the effect on patients of a preparation called "salvacid." According to Thom this preparation contains *fel tauri sicca*, *Thujoncholyglyzin*, acetylglycocholic acid, together with calcium carbonate and sodium bicarbonate.

OBSERVATIONS

Based on these considerations we began the administration of desiccated ox bile to patients with peptic ulcer in January 1934 and continued its use over a period of two years. We wished to use a product of bile which would be convenient to give and at the same time would be as similar to fresh bile as possible. Because the moderately high temperature to which the usual preparations of bile are subjected might change the quality of its ingredients, we asked the Burroughs and Wellcome Company for suggestions to overcome this difficulty. After some study their laboratory found that by mixing the bile with exhausted licorice root one could dry the preparation at a temperature below 38 degrees centigrade. They gave us enough of this material to carry out the study reported herein. We should like to take this opportunity to express our appreciation of the cooperation and many courtesies extended by the various members of the company.

The bile was enclosed in gelatin capsules containing 0.3 gram, 0.5 gram, and 0.75 gram. The larger capsules proved unsatisfactory because some of the patients found them difficult to swallow. Ultimately, we used only the 0.3 gram capsules.

It was difficult to know how much bile should be given in treating these patients. As previously stated, if peptic ulcer depends upon a disturbance in the biliary secretions, this disturbance may be in the nature of a quantitative or of a qualitative abnormality. Except for the work of McClure and Huntsinger, which suggests that a qualitative difference occurs in the bile of patients with ulcer, there is little information on the subject. We had no other choice than to give as much as a patient could tolerate. Before beginning the treatment of patients with ulcer, we determined the amount of bile that could be tolerated by individuals with no gastrointestinal disease. Eighteen such patients who were on the medical wards of the Peter Bent Brigham Hospital were given increasing amounts of bile. It was found that individual patients varied in the amount which they could tolerate. On the average these persons could take 3.0 grams of our material a day if given in divided doses. A few were able to tolerate 4.0 grams but some were upset by 2.5 grams. The ill-effects consisted of anorexia, nausea and slight diarrhea. Occasionally a patient complained of slight epigastric burning. We utilized these data to establish an upper limit of dosage of 3.0 grams per day in our patients with ulcer, and attempted whenever possible to give this maximum amount. Nearly all the patients were able to take

daily a dosage of two capsules of 0.3 gram of bile every two hours for five doses

Altogether we have treated 40 patients with peptic ulcer. As established by the roentgen-ray, four had gastric ulcers, 32 had duodenal ulcers, and four had both. All the patients were seen and followed in the gastrointestinal clinic of the out-door department of this hospital, and except for one or two instances, they were ambulatory throughout the course of treatment. The duration of symptoms varied from 1 month to 25 years, with an average of 5.7 years. Ten of the group had received no previous treatment, whereas the others had been given various types of ulcer therapy. We endeavored to limit the treatment to therapy with bile only, but this was not always possible. Based on this fact, the 40 cases have been divided into two groups: (1) those whose therapy consisted of bile only, and (2) those who received some alkaline treatment in addition to the bile. Both groups were given a normal diet. It seemed wise to give these patients some kind of menu in order to guard against foolish excesses. Having used this diet for many years, we know that it will not of itself control the symptoms of ulcer.

A few patients complained of epigastric burning shortly after the ingestion of a capsule. We found this could be eliminated by the use of a full glass of water at the time the capsules were taken.

Group 1—Patients Treated with Bile Alone There were 23 patients who were treated with bile alone. These individuals had had symptoms of ulcer from 1 to 22 years, with an average of 4.5 years. The duration of treatment varied from one week to two years (average 6.18 mos.), depending upon the results and the degree of cooperation obtained. The treatment in all instances was continuous. None of the patients was treated longer than two years. The results have been classified into four groups. The first consists of seven patients who had "excellent" results (Followed for an average of $7\frac{1}{2}$ mos.). These individuals were promptly relieved of all symptoms and continued to be free from complaints throughout the course of their treatment with bile. The second group comprises seven cases that had "good" results, with definite amelioration of their discomfort, they did have, from time to time, mild symptoms that could be recognized as coming from the ulcer. (This group was followed for an average of $7\frac{1}{4}$ mos.) In the third group were three patients who had "fair" results, that is, they had less trouble than before the treatment was begun, but the results were not satisfactory from the point of view of either the patient or ourselves. (These were followed for an average of $6\frac{1}{2}$ mos.) In the fourth group were six patients who are classified as "failures" in that they did not receive any benefit whatever. Some of these refused to follow the treatment long enough for us to judge whether they would have received any improvement if the treatment had been continued longer. (These were followed for an average of $2\frac{3}{4}$ mos.)

As in all chronic diseases, the evaluation of the effect of therapy is very difficult in peptic ulcer. Our results would imply that bile is not a specific cure for the disease. However, as we followed these cases, the results were so striking in certain individuals that they seemed worthy of a careful analysis. The first thought which occurred to us was that the difference in results might be due to psychotherapy, a most important factor in the institution of any new form of treatment. We tried to avoid enthusiastic suggestions as much as possible. In addition, we attempted to classify these patients according to temperaments, without finding any striking differences in the groups. We could not convince ourselves that the difference in results could be explained on this basis, and, if a psychic influence played a rôle, we were not able to detect it.

The factor of previous therapy for the ulcer was considered next as of possible significance. Of the seven patients who had "excellent" results, six had received no previous kind of treatment. From the seven with "good" results, three had had no previous ulcer therapy. The nine patients who had only "fair" results or had failed to receive any benefit, had all had some kind of other treatment for the ulcer. This would suggest that the opportunity to compare the effectiveness of two kinds of treatment tended to make the patients with the previous therapy less satisfied with the bile treatment. Possibly, these patients were more than normally resistant to any form of treatment.

An attempt to correlate the results with the severity of the process has not been enlightening.

The range of acidity as determined by gastric analysis in the four groups was surprisingly constant. The average for the highest acidities was as follows:

| | | | | |
|-------------|-----------|------|------------|-----|
| "Excellent" | Free Acid | 44°— | Total Acid | 55° |
| "Good" | " " | 49°— | " " | 65° |
| "Fair" | " " | 42°— | " " | 58° |
| "Failures" | " " | 53°— | " " | 67° |

The incidence of night pain, which is thought by many to be an index of secretion, was the same in the four groups.

Gastric analyses were obtained before and after the therapy in nine patients of this group who had been treated with bile alone. It is of interest, although its significance is not clear, that the gastric acidity was greater in all but two of these patients after they had received bile for some time. This was true of three patients who had "excellent" results, as well as of the others.

Other comparative studies do not show any essential difference in the relative severity of the disease in patients who had poor results and in those who had satisfactory results. The duration of symptoms before the treatment with bile was essentially the same in all groups, an average of about 4.5 years. The incidence of such complicating symptoms as nausea, vomit-

ing, and bleeding, was likewise similar in the various groups. The only observation that might suggest a difference in severity was the incidence of seasonal attacks. Six of the seven patients who had "excellent" results had definite seasonal attacks of pain, and under bile therapy these patients went without symptoms through the time of year when they expected an attack. Five of the seven who had "good" results had seasonal attacks of pain and four of the five were carried through successfully with bile. In contrast to this, only two of the nine patients who had poor results with the bile treatment had a seasonal occurrence of ulcer symptoms and neither of these two was relieved. The incidence of seasonal occurrence of symptoms, then, is the most striking difference between the patients who received satisfactory results and those who did not. We are not prepared to say on what this difference rests.

Group 2—Patients Treated With Bile Together With Some Alkali

There were 17 patients who received an alkaline Sippy powder (calcium carbonate 0.6 gram, sodium bicarbonate 2.0 grams) after each meal, in other words, three powders a day, in addition to the bile capsules. Some of them also took a half glass of milk and cream once between meals, that is twice a day. It seems necessary to discuss these patients in a separate group because they were receiving more than one type of therapy and for that reason the results were more difficult to evaluate. The additional powders were given in most instances because the bile was not giving complete relief of symptoms, or because a few requested them from fear that ulcer symptoms might return. The milk was given to those few who requested it inasmuch as they liked the habit of a forenoon and afternoon drink.

This group was followed from 1 to 12 months (average 6.2 months). The length of observation was correlated to some degree with the response to therapy. On the whole these cases did not do as well as those on bile alone. However, we have classified them under the same criteria as the group treated with bile only.

(1) Two patients had "excellent" results over a period of 10.5 months observation. (2) Five patients had "good" results over an average period of eight months. (3) Six patients had "fair" results over a similar period of observation, and (4) Four patients were "failures" remaining under treatment only six to eight weeks.

Reasons for the difference in results in this group were as difficult to detect as in those who received bile alone. The duration of symptoms before treatment was as follows: "excellent"—6 years, "good"—6 years, "fair"—5.5 years, "failure"—12.5 years. The average for the group is about 7.5 years. All but one of these patients had received a previous treatment for ulcer, the one exception fell into the group of "failures." The difference in results in this instance cannot be attributed to a comparison between the effectiveness of bile and the previous type of therapy.

An attempt to estimate the emotional and nervous reactions of the patients in this group casts no light upon the difference in results. The gastric analyses showed similar findings with the exception of the "fair" group, in which the acid values were distinctly lower. The average acid values of gastric juice for these patients were as follows:

| | | | | |
|-------------|-----------|------|------------|------|
| "excellent" | Free Acid | 67°— | Total Acid | 70° |
| "good" | " | 64°— | " | 111° |
| "fair" | " | 29°— | " | 45° |
| "failure" | " | 66°— | " | 82° |

It is striking how similar these figures are to those in Group 1. Five patients in this group treated with bile plus small amounts of alkali had gastric analyses done before and after the treatment, without, in this instance, any essential change in the values.

Thirteen of these 17 patients had a distinct history of seasonal ulcer distress of which eight were carried through this period without symptoms. It is striking that the four patients in whom treatment failed in this group had seasonal attacks of symptoms, as opposed to the failures in Group 1 in which only two of nine cases with poor results gave a seasonal history, the other seven having continuous symptoms.

No difference could be elicited between the results on the basis of the type of symptoms from which the patient suffered. The incidence of night pain was about the same in each class and this was true also of the incidence of bleeding.

DISCUSSION

It may be stated as almost an axiom, and certainly as an impression from observations, that *one can feed patients with ulcer disease almost anything and a certain number will respond favorably*. The literature reports good results from numerous and diverse methods of treatment. These good results may be explained by the fact, as pointed out by Emery and Monroe,²¹ that a spontaneous alleviation of symptoms may extend over a long period of time in as many as 48 per cent of individuals with ulcer. Because the symptoms are easily controlled, in most instances, there is only one criterion on which to judge results. That is the prevention of a relapse. Unfortunately, we have no other method of judging the effectiveness of therapy in this disease, as we have in pernicious anemia, in which the increased number of reticulocytes is an index of the response to treatment.

From the results obtained in the treatment of these 40 patients with peptic ulcer, we must conclude that desiccated ox bile is not a specific cure for the disease. A satisfactory result occurred in only 52.5 per cent which is not much better than can occur spontaneously. This seems to rule out a disturbance in the biliary secretion as a cause of peptic ulcer in man.

However, it is our impression that the administration of bile will relieve symptoms in a definite number of patients, and this impression was

strengthened by the prevention of a seasonal recurrence in 73 per cent of the patients. The mechanism of the favorable effect is not clear. It does not seem probable that the buffering effect of only 0.3 to 0.6 gram of bile in a dose would be sufficient to explain the relief. This is supported by observations made on two cases in which aspiration of stomach contents was done shortly after the ingestion of a capsule of bile. In neither instance was there noticed an appreciable effect on the gastric acidity. Furthermore, in none of the cases, whether the responses were good or not, was there a reduction in the values of free and total acid in the gastric analyses. In fact, some of the cases with "excellent" results in Group 1 had higher values in the gastric analyses after the period of observation with bile than before, although they had suffered no symptoms. These observations forced us to conclude that the beneficial results obtained with this form of treatment were probably not due to lowering of the gastric acidity.

It is a common observation that many patients with peptic ulcer tend to have constipation. The alleviation of this symptom by the bile treatment was observed and reported spontaneously by many of the patients. Upon questioning the others who had not expressed themselves, we found that all of them had more regular bowel habits as a result of the treatment, many being relieved of a cathartic habit. Only one patient developed any symptoms comparable to those experienced by the control cases when we established the dosage of the material. Only one other individual developed diarrhea at any time, and it was promptly relieved by a slight reduction in the dose and the patient continued free of ulcer symptoms. We have found that the ability of bile to relieve symptoms is useful in those patients who have kidney disease or renal calculi in addition to an ulcer, in whom one may hesitate to push alkaline therapy. There were two patients in this series from whom renal calculi had been removed. Both patients were given only bile. They both responded very well and remained free of ulcer distress for over a year during which they have been followed.

We have pointed out previously¹⁵ that there is no necessary correlation between the pain of ulcer disease and the roentgen-ray demonstration of a crater. This is again illustrated by three of the patients in Group 1 who were treated with bile alone. All three had responded well to the treatment. Some six to eight months after the initial roentgen-ray demonstration of a crater in the duodenum and the institution of bile therapy, repeat gastrointestinal studies were carried out. Although these three patients had been free from ulcer symptoms for these months, barium studies revealed a crater still present. Subsequent observation and studies have adequately shown that these were not instances of carcinoma.

Although bile was administered to these patients in order to learn its effect on the disease of ulcer, certain other observations were made. With the present universal interest in the study of hypertension and of means for its treatment, bile therapy too has been suggested -- as a method of lowering the blood pressure. We observed the blood pressure in six patients with

hypertension The ingestion of 20 to 30 grams daily of our preparation caused no changes in the blood pressure level that could not be accounted for by the normal daily variations There was no lowering of blood pressure in a few cases without hypertension

It has been reported^{23, 24} that perhaps an excess of bilirubin in the circulation or an increased amount of bile salts in the blood, or both, accounts for the analgesic effect of jaundice on the symptoms of arthritis Because of this observation, Sidel and Abrams have given bile salts to patients with arthritis with some gratifying results We had under observation for ulcer, one patient who had a moderate degree of infectious arthritis, to whom we gave the bile therapy His ulcer symptoms responded fairly well but his joint pains remained unchanged

SUMMARY AND CONCLUSIONS

Experimental peptic ulcers in animals which appear similar to those occurring in man have followed interference with the flow of bile into the duodenum or damage to the liver In man, ulcers have been observed associated with liver disease, and in a few instances qualitative abnormalities in the bile have been reported in cases of duodenal ulcer These facts, plus the hypothesis that a deficiency may be the important factor in the disease of ulcer, prompted us to administer desiccated ox bile to patients with peptic ulcer

A total of 40 patients with ulcer has been treated with bile over periods as long as two years Four patients had gastric ulcers, 32 had duodenal lesions, and four had both The 40 cases were divided into two groups (1) 23 patients who were treated with bile only, and (2) 17 patients who received some alkaline treatment in addition to the bile

The results from this treatment were as follows Nine patients (22 per cent) had "excellent" results, 12 patients (30 per cent) had "good" results, 9 patients (22 per cent) had "fair" results, and 10 patients (25 per cent) were "failures" These figures are such as to exclude desiccated ox bile as a specific cure for the disease However, bile may be useful as a means of relieving the symptoms of certain patients, in whom the use of alkalis is contraindicated

EXERCISE TESTS AND THE ELECTROCARDIOGRAPH IN THE STUDY OF ANGINA PECTORIS¹

By MORRIS E. MISSAL, M.D., F.A.C.P., *Rochester, N. Y.*

DESPITE the high incidence of angina pectoris² and its varied causes, a relatively large number of patients, after most careful routine physical examination, roentgenological investigations, and routine electrocardiographic studies (including chest leads) yield findings within normal or nearly normal limits. In such cases the diagnosis must be made upon the description of symptoms obtained from the patient. According to Burnett¹ one-third of the patients, and according to the experience of Paul D. White² 20 to 25 per cent of the patients having angina pectoris fall within this group.

In many instances the history is so typical that a diagnosis of angina pectoris may be made with fair certainty in spite of the absence of objective findings. However, where the physician is confronted with the possibility of such a serious clinical entity, and especially where anxiety, fear, or suggestion are confusing factors, the desirability of objective evidence will be readily admitted. Such information is also important where atypical symptoms confuse the diagnosis. In addition to pitfalls in diagnosis, there are difficulties in estimating accurately the severity of this disease, the progress of the condition, and the results of therapy, all of which make objective evidence the more desirable.

In an attempt to supply this need we have been studying the effect of measured amounts of exercise on the symptoms and electrocardiograms of a number of patients. In some of the subjects the diagnosis was previously uncertain, in others a diagnosis of angina pectoris had been made unequivocally. Before describing our method and results, it will be profitable to examine the work already done in this field.

Transient changes in the electrocardiogram have been described by various investigators³⁻²⁰ during spontaneous as well as induced attacks of angina pectoris. Most of the described changes have concerned the direction of the T-waves, and the relationship of the RT or ST interval to the iso-electric line. Other subjects have shown, either alone or in conjunction with the above changes, transient bundle branch block (Bousfield¹¹), transient auricular fibrillation (Parkinson and Bedford¹⁰, Arrilaga¹²), premature contractions (Hall⁸), lowering of the QRS voltages, and inversion of the T-waves (Vela¹³).

* Received for publication September 20, 1937.

From the Department of Medicine, University of Rochester, School of Medicine and Dentistry and the Strong Memorial and Rochester Municipal Hospitals, and the Cardiac Clinic, Rochester General Hospital, Rochester, N. Y.

[†] We have considered angina pectoris to be a symptom due to deficient circulation of the myocardium, rather than a disease entity in itself.

Siegel and Feil¹⁶ have shown that such changes in the electrocardiograms do not accompany pain arising from other causes such as uterine contractions in labor or from gall-bladder or renal colic. In one patient with a gastric ulcer and paroxysmal epigastric pain, slight depression of the T-wave occurred, which varied in successive beats and was perhaps related to changes in the axis of the heart.

Whitten and Herndon¹⁴ have carefully analyzed a series of 50 normal controls, 15 cases of angina pectoris, and a small series of patients with heart disease other than angina pectoris. This work included a study of electrocardiograms (conventional three leads) taken at rest and immediately after exercise. Eight (53 per cent) of their 15 angina pectoris patients showed some of the following changes in the electrocardiograms which were not seen in the two control groups:

- “(a) Upright T_1 and T_2 became inverted,
- (b) Inverted T_2 became upright (Also in angina group that did not develop pain on test exertion),
- (c) Iso-electric T became upright (Also in angina group that did not develop pain on exertion),
- (d) Upright T_2 became diphasic,
- (e) Development of upward convexity of the RS-T interval ending in an inverted T (Coronary T-wave),
- (f) Increase in the “positivity” of the RS-T of more than 0.1 mm produced by exercise in an already elevated RS-T,
- (g) The only Q greater than 1.0 mm in amplitude that disappeared on exercise was in the angina group.”

Many who have worked in this field have commented that in some of the normal subjects after such strenuous exertion as marathon running, there may occur a depression of RT_1 and RT_2 , or RT_2 and RT_3 to as much as 1.0 mm below the iso-electric line. This finding frequently occurs during attacks of angina pectoris. However, there is a tremendous discrepancy between the amounts of work required to produce such changes in these two groups of subjects, and furthermore, the underlying mechanism is probably the same, namely myocardial anoxemia.

Wood and Wolferth⁷ described transient changes after exercise in the RT intervals and T-waves of 15 (50 per cent) of the 30 cases of angina pectoris. Goldhammer and Scherf¹⁷ reported similar changes in 30 (75 per cent) of 40 patients with angina pectoris, and Duchosal and Henny⁸ found the test positive in 11 (58 per cent) of 19 true cases, doubtful in one, and negative in seven cases of angina pectoris. These last workers observed the test to be positive in seven of 24 doubtful cases of angina pectoris, doubtful in four, and negative in 13 cases.

It will be observed that a considerable percentage of seemingly typical cases in each of the above series showed negative electrocardiographic (3 lead) tests after exercise. Possible explanations are (1) insufficient exer-

cise in those who did not develop pain, (2) mechanisms other than anoxemia being factors, or (3) the possibility that the process was in so-called "silent areas" not reflected in the conventional three leads. It occurred to us that additional information might be obtained from a study of the effect of exercise on the chest leads as well as on the conventional three leads.

So far as we have been able to learn from a survey of the literature, Katz and Landt¹⁸ are the only workers who have studied the effect of exercise on the chest leads as well as the conventional three leads. Personal communications^{21, 22} from some of the workers in this field indicate that no work has yet been published on the effect of exercise on the chest leads of normal subjects. The series of Katz and Landt consisted of 20 ambulatory angina pectoris patients. They found transient changes in the chest leads in 11 of the 20 patients, in two of this group the changes occurred in the chest lead alone, in the other nine patients changes occurred in all four leads. That the amount of exercise (dumb-bell swinging while recumbent) may have been insufficient is suggested by the fact that pain occurred in only 13 of the 20 subjects. After reviewing their tables, we remain of the opinion that some of the changes they have described are not typical of angina pectoris. According to our own experience certain of these changes may occur in the electrocardiograms of normal subjects after exercise. We refer especially to the deepening of the normally inverted T-wave in the chest lead. Likewise, a slight depression of the RT interval may occur in any lead of some few of the normal subjects, even to 1.0 mm ($\frac{1}{10}$ millivolt) below the iso-electric line.

We have been able to confirm the experience of most of the other workers³⁻²⁰ in this field concerning the significance of transient inversion of an upright T₁ and T₂, or an upright T₂ and T₃, and/or significant changes occurring in the ST segments, after exercise, in the electrocardiograms of subjects with known or suspected angina pectoris. We are convinced that these changes do not occur in normal subjects and that these findings must be considered positive evidence of myocardial ischemia. Moreover, our studies of the chest leads of angina pectoris patients after exercise have led us to believe that *the same significance must be given to a shift of the RT segment in the negative direction or the temporary disappearance of the Q-wave in this lead, or a change from a normally positive T-wave to a negative one.* These changes have never been seen in our normal subjects. In the series of Katz and Landt¹⁸ the upward (negative) shift of the RT in the chest lead occurred four times in 20 tests: three times with changes in the conventional lead and once alone. Whitten and Heindon¹⁴ found one patient among 15 with angina pectoris in whom a Q-wave in the conventional leads greater than 0 mm in amplitude disappeared after exercise.

We are collaborating with Drs. Grant Otis and Joseph K. Bradford in a study of the effect of exercise on the chest lead as well as on the conventional leads of a group of normal subjects. This work will form the basis of another publication.

So far we have studied the effect of exercise on the conventional as well as Lead V of a group of 40 normal individuals varying in ages from 20 to 55. After such exertion as rapidly ascending from three to six flights of stairs, we have noted in addition to the temporary increase in rate the following transient changes in the electrocardiograms. In some, the T-waves increased in voltage, in others, they decreased. A few showed changes in the RT intervals in the negative direction to 1.0 mm below the iso-electric line. A few showed slight changes in the electrical axis. In none of these subjects was the direction of the T-wave changed, nor did we find any of the changes in the chest lead described in our angina pectoris patients during induced attacks of pain.

METHOD OF STUDY

Any method used for the study of pain and other symptoms in patients with coronary disease or allied conditions of myocardial ischemia should be reasonably accurate and as nearly free as possible from untoward effects.

Such a method of study we believe available in the use of the so-called "Standard Two-Step," utilized originally by Master and Oppenheimer²³ in a study of the response of pulse and blood pressure to a standard amount of exercise. It was used later by Riseman and Stern²⁴ in their studies on the amount of work required to produce attacks of angina pectoris.

The apparatus used is a two-step staircase. This apparatus has many advantages. The exercise of walking up and down steps is a familiar one and requires only brief directions. The amount of exercise can be readily varied and regulated. If the patient should develop any symptoms, the activity can be immediately stopped and the patient rested and studied in the very room in which the exercise is performed. Its comparative mobility, low cost, and ease of storage are additional advantages for the physician in private practice. The number of foot pounds of work performed may be estimated roughly by multiplying the patient's weight by the height of the staircase ($1\frac{1}{2}$ feet) and the number of trips performed (a trip consisting of a single ascent and a descent). This is inexact, however, for it ignores the work done in descent of the stairs. We have been able to confirm by repeated tests the relative constancy of effort required to produce the earliest symptom of discomfort in the individual exercised. Patients were never told their exercise tolerance. In this way the element of suggestion was lessened.

In our opinion the temperature of the ordinary office does not vary sufficiently to affect materially the amount of work necessary to produce discomfort. Wayne and Graybiel²⁵ also indicate that the temperature of the environment is not a very important factor. Riseman and Stern, however, have shown that in some patients a low environmental temperature is prone to precipitate pain with less effort. This particular point deserves further study in view of recent work indicating the effect of cold on the blood pressure.²⁶

Riseman and Stern used as their "end point" the amount of exercise producing sufficient pain to stop the patient. Because of our inexperience with the method and fear of possible danger to the patient, we have taken as our "end point" (after our first few tests) the earliest discomfort indicated spontaneously by the patient.*

*The exact nature of pain production in the heart is not clear. From the work of Lewis, Pickering, and Rothshild²⁸ one learns that the pain following the contraction of skeletal muscle during ischemia (tourniquet) is associated with actual dilation of blood vessels.

The bulk of experimental work favors the view that pain is due to chemical irritants arising from reduction or cessation of blood supply. Briefly summarized, the evidence for the so-called "ischemia theory" follows:

(1) Ligation of a coronary artery branch results in changes of electrical potential in the area affected and produces characteristic changes in the electrocardiogram.^{29, 30} When the arteries studied are only clamped, these changes are temporary and are quickly reversed upon restoring continuity of the artery.^{31, 7} The changes referred to are greater inversion of previously negative T-waves in some experiments and the production of a high take-off in the ST complex in others. In unanesthetized animals objective evidence of pain occurs.^{32, 33}

(2) Similar electrocardiographic changes occur during attacks of angina pectoris and disappear between attacks.^{3, 20}

Three possibilities present themselves:

- (1) That lack of oxygen is itself the stimulus,
- (2) That some condition resulting from anoxemia is the stimulus,
- (3) That irritable substances resulting from the metabolism of muscle, which are not washed away for lack of blood, constitute the stimulus.

The theory that pain is related in some way to anoxemia is supported by the following:

(1) Attacks of pain occur in conditions in which the oxygen content of the blood is low as in anemia⁴⁴ or in carbon monoxide poisoning.³⁵

(2) Angina pectoris frequently occurs in the presence of aortic insufficiency (low diastolic pressure) or in patients known to have had coronary thrombosis.

(3) Attacks of pain can be induced in susceptible subjects by rebreathing low oxygen mixtures or by strenuous exercise which creates a state of anoxemia generally referred to as "oxygen debt."^{19, 36, 37, 38} Such attacks have been found to produce characteristic electrocardiographic changes resembling those following coronary occlusion. Katz,³² however, has demonstrated that the electrocardiographic changes and production of pain do not necessarily go together. For in many instances exercise or relatively low oxygen mixtures caused the electrocardiographic changes without pain in normal subjects or even in patients with a history of anginal attacks.

Lewis^{39, 28} concluded after studying the development of pain in contracting skeletal muscles:

- (1) That special metabolic products (*P*-factor) formed by contracting but not by resting muscles stimulate pain endings,
- (2) That the locus of their action is in connective tissue and not within muscle cells, and
- (3) That the chief value of a good circulation resides in its ability to flush these substances away and not in its ability to supply oxygen. However, Kissin³⁸ offers evidence that oxygen lack may be an important factor in the production of pain. He observes that anoxemia produced by breathing low oxygen mixtures reduced the time necessary to produce pain in an exercising limb but the degree of anoxemia had to be rather severe in order to become a factor in the production of pain in an exercising muscle.

Katz³² concludes: "It would appear that the stimulus for pain is a metabolic product (or products) which can readily diffuse into the blood stream and which can be quickly altered in the presence of an adequate supply of oxygen. The accumulation of this product is dependent upon the amount and character of the physiological work and the efficiency on the one hand, and the quantity of oxygen and blood supply on the other. When this substance reaches a concentration above the threshold of the pain end organs, pain results. The chemical product appears to be acid in character, or at least one that is additive with acid substances and is 'neutralized' by alkaline substances. In all probability it is some substance like lactic acid or phosphoric acid formed during the catabolism of muscular activity."

Riseman and Stern studied over 500 induced attacks in 57 patients diagnosed as suffering from angina pectoris. No untoward effects were discovered from the exercise or the induced attacks. Other factors affecting the amount of exercise required to produce pain in a given individual were found to be excitement, recent ingestion of food, previous medication (nitrates), recent attacks of pain, and recent exertion. Thus far we have studied 94 attacks in 40 patients by this method. None has experienced any inconvenience or ill effect, and all have expressed willingness to repeat the test. In every instance the symptoms lasted less than four minutes and disappeared spontaneously.

In addition to determining the amount of exercise necessary to produce discomfort in these patients, we have also observed the effect of the exercise and resulting pain on the electrocardiogram, conventional three leads as well as chest lead. The position of electrode on the chest was marked and the identical area used in the subsequent tests.* In all instances an electrocardiogram was taken after a rest period of 30 to 60 minutes. The importance of this rest period is pointed out by Duchosal and Henny⁶ who made the following interesting observation. An electrocardiogram was taken of a patient after a night's rest in bed. During the next hour and 25 minutes, the patient was permitted to walk around his bed a few times, following which he rested 35 minutes. Another electrocardiogram was then taken. No pain occurred during the two hour interval, yet the second electrocardiogram showed a distinct drop of the T-wave and a slight drop of ST when compared with the earlier (basal) electrocardiogram. We feel that it is desirable to use the same basal conditions as for metabolic determinations.

The speed of the string type electrocardiograph made it preferable for our studies. Not infrequently, we have been able to take a four lead electrocardiogram (standard leads and one chest lead) in 75 seconds (10 to 12 cycles per lead) whereas trials with two of the older amplifier type machines required from six to ten minutes for similar determinations. Both timings were made with the electrodes attached to the subject and, in the case of the amplifier type machine, after the current had been turned on for a sufficient period. The time loss is due to oscillations of the light beam as connections are made for the various leads. In some of the newer amplifier machines, this difficulty seems partially corrected. Ease of standardization is an advantage of the amplifier type apparatus.

The necessity for speed arises from the importance (emphasized by Scherf²⁷) of comparing with the resting electrocardiogram the tracings taken immediately after exercise and at stated intervals following. The advantage of speed of operation is well illustrated in the electrocardiograms of our first patient (Figures 1 *A* and *B*). Significant changes were seen

* The right arm electrode was held at the left fourth intercostal space near the sternal border and the left leg electrode used as the indifferent electrode.

in the tracing taken immediately after exercise. The tracing taken five minutes after exercise disclosed only insignificant changes with reference to the resting electrocardiogram, considering that inversion of T_c may occur in normal subjects after exercise.

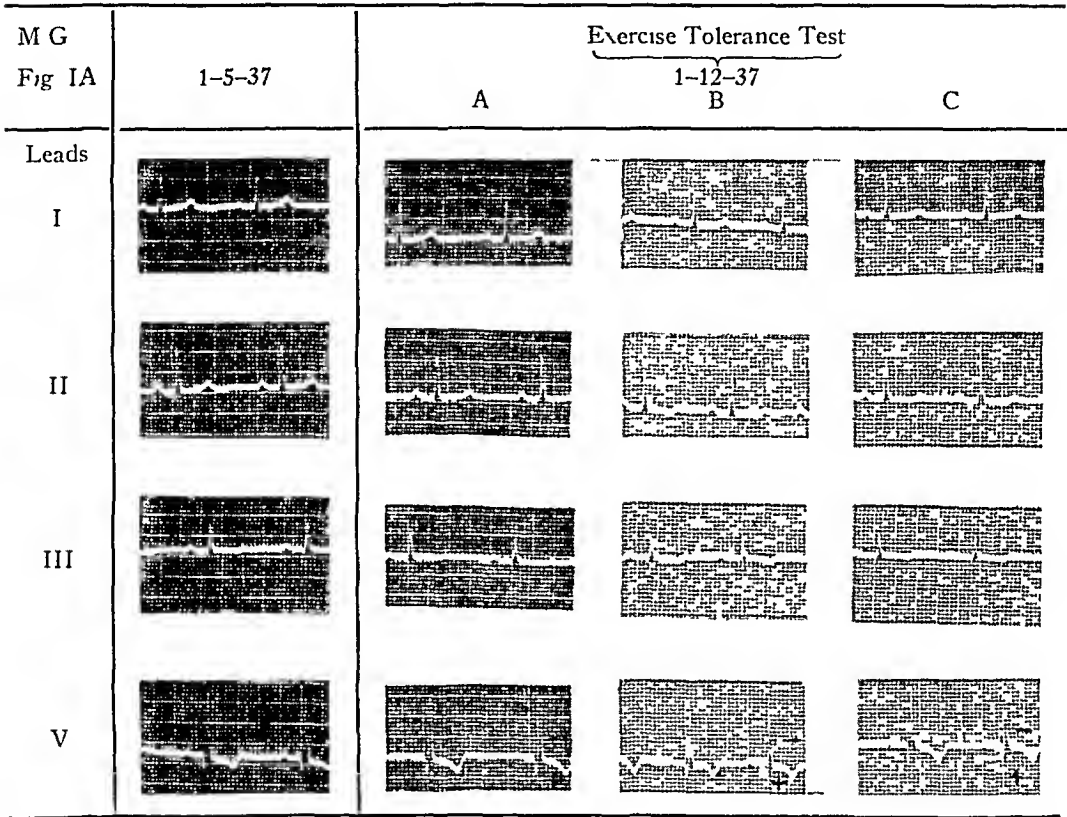

FIG 1-A January 5, 1937 Routine electrocardiogram shows no preponderance of either ventricle, normal T-waves, and normal RT intervals. Rate is 60. PR measures 0.20 second. Normal chest lead.

January 12, 1937 Exercise tolerance test shows

- A Resting electrocardiogram is identical with the tracing taken on January 5, 1937. Rate is 60.
- B Electrocardiogram taken immediately after exercise, consisting of 27 trips on the standard steps in 2½ minutes. Rate is 68. Note changes in T and T_2 . T_2 has become diphasic and RT_2 has dropped below the iso-electric line. T_1 has become inverted. T_c has dropped to 10 mm. The chest lead shows very little change from the chest lead of the resting electrocardiogram. The T-wave in this lead reaches but 2.5 mm below the isoelectric line as compared with 4.0 mm in the resting tracing.
- C Electrocardiogram taken five minutes after the exercise was finished. Rate remains at 68. The tracing has almost returned to the resting appearance. Note the return of RT_c to the isoelectric line. T_1 is still lower than in A. The chest lead is identical with the one in A. The location of the chest electrode is the same for electrocardiograms A, B, and C.

Electrocardiograms of Patient M G. All electrocardiograms have been taken with the standardization of 1 cm equal to 1.0 millivolt. The connection for Lead V is made between the electrode placed at the left sternal border and the left leg.

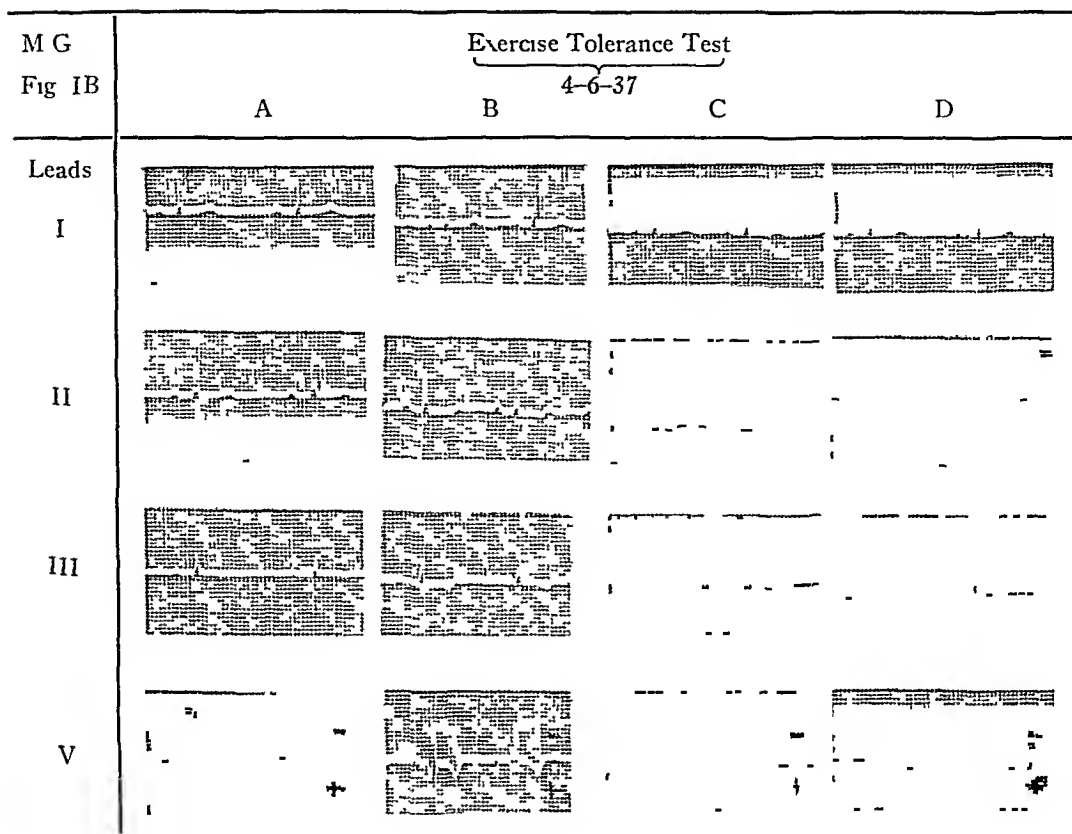

FIG 1-B April 6, 1937 Exercise tolerance test shows

- A* Resting electrocardiogram. Rate 54 Sinus bradycardia PR measures 0.22 second T_1 measures 12 mm T_2 measures 10 mm The chest lead is within normal limits
- B* Taken immediately after 23 trips on the standard steps No symptoms noted as a result of the exercise Rate rose to 66 T_1 remains unchanged T_2 is diphasic and associated with a lowering of RT. T_3 is sharply inverted The chest lead is unchanged
- C* Electrocardiogram taken three minutes after the exercise No change in rate More marked changes in T and T_1 T_1 is also slightly lower
- D* Electrocardiogram taken 10 minutes after the cessation of exercise shows a return to the resting electrocardiogram (See electrocardiogram *A* above)

CLINICAL APPLICATION OF WORK TESTS

Case History 1—Showing marked electrocardiographic changes after slight exercise without production of pain Patient has coronary disease, a low basal metabolism, and a hyperchromic anemia

Miss M G, a 56 year old graduate nurse, presented herself for examination on March 18, 1937, because her "heart was not strong enough to carry on." Although she considered that the onset occurred suddenly in April 1935, during a period of great anxiety and overwork, closer questioning revealed that for 10 years she had had a "fatigue pain" under the left scapula. This was definitely related to overexertion, it would occur at the height of activity, and disappear after one-half hour's rest.

One night in April 1935, she noted an irregular beating of the heart and a "fear of sudden death." Pain suggesting the acute closure of a coronary artery was not noted. Also about this time she was awakened by severe dyspnea. This was immediately and completely relieved by standing. Although she was able to assume her duties that day, her physician insisted upon her staying away from work for a period of time. She remained at home for 11 weeks, but during this time the re-

sponsibilities of caring for an invalid father interfered with rest. About the same time there occurred a gradual change in the back discomfort. This "fatigue" pain now would radiate to the left breast and substernal region. Nitrites have never been used.

Of interest in the past history was an anemia discovered in 1928 (red cells, 2,800,000, hemoglobin, 50 per cent). Her basal metabolism was 4 plus. A gastrointestinal roentgen-ray series was negative. Cholecystograms were not made.

For the past two years she has had great difficulty keeping warm and would use hot water bottles in bed. At night twitching of the feet and thighs disturbed her.

Since 1934 she has taken thyroid extract gr $\frac{1}{2}$ (0.03) (Parke-Davis) daily and a preparation of liver extract. A blood count on 3-30-37 was reported: hemoglobin, 86 per cent, red cells, 3,999,000, and white cells, 5,400. Another on 1-30-38 showed hemoglobin, 73 per cent, R B C 3,900,000 and the smear showed macrocytosis, anisocytosis and a rare basophilic red cell. A gastric analysis has not been done because of the underlying cardiac condition. The patient has recently been started on dilute hydrochloric acid with meals and injections of a potent liver preparation.

Physical examination showed: Weight was 177½ pounds. Height was 59½ inches. There was a slight yellowish tint of the skin, but no signs of myxedema. The ocular fundi were negative. The peripheral arteries were soft. Blood pressure was 134/80. The heart was normal in size both on physical examination and by roentgen-ray. The lungs and abdomen were negative.

Her basal metabolic determinations are listed:

| Date | Basal Rate | Remarks |
|---------|------------|---|
| 4-9-37 | -40% | Thyroid omitted for 10 days |
| 4-23-37 | — | Started thyroid (Armour's) gr 1 (60 mg) daily |
| 5-7-37 | -40% | Taking thyroid—same dose |
| 6-4-37 | -36% | Taking thyroid—same dose |
| 7-10-37 | -31% | Taking thyroid—same dose Feeling much better |
| 9-2-37 | — | Exercise test |
| 9-4-37 | -33% | Same dose thyroid |
| 12-4-37 | -31% | Improvement maintained Thyroid reduced to gr $\frac{1}{2}$ (30 mg) |
| 1-28-38 | -35% | Feeling about same On same dose thyroid |
| 2-1-38 | — | Exercise test |

Other laboratory findings were: Blood calcium was 10.8 mg per cent, phosphorus, 3.1 mg per cent, cholesterol, 625 mg per cent and N P N, 37 mg per cent. Blood Wassermann and Kahn tests were negative.

Resting electrocardiograms taken at intervals since March 1935 had shown inconstantly a slight prolongation of auriculo-ventricular conduction to 0.22 second. Lead V was normal. Because her symptoms so overshadowed the objective findings, we obtained permission from Dr B. J. Slater to make exercise studies. In this we received the hearty cooperation of the patient.

Exercise Tolerance Tests

| Date | No of Trips | Time | Remarks |
|---------|-------------|------------|---|
| 1-12-37 | 27 | 2½ minutes | No pain felt. Admitted some dyspnea after questioning (figure 1 A). |
| 4-6-37 | 23 | 2¼ minutes | No pain or dyspnea (figure 1 B). (Test taken to study the changes in the absence of pain.) (BMR—40 per cent.) |
| 9-2-37 | 23 | 2¼ minutes | Patient asked to stop the test because of marked chest pain. Had taken desiccated thyroid for 2 months (BMR—31 per cent, —33 per cent). |
| 2-1-38 | 25 | 2½ minutes | Slight shortness of breath. Patient asked to stop because of tightness in chest. |
| | 29 | 2¼ minutes | No pain or objective dyspnea. |

Although compatible with a diagnosis of coronary artery disease, this patient's history was remarkable for the meagerness of objective evidence implicating the circulatory system. It is probable that her anemia contributed greatly to her cardiac symptoms and that her marked symptomatic improvement during the past six months may be partially explained by the increased oxygen carrying capacity of the blood, consequent to the improvement of the anemia. The anemia itself may be partially the result of hypothyroidism. The cardiac symptoms in the presence of a low metabolic rate deserve comment in view of the recent vogue for completely removing non-toxic thyroid glands. These operations have been done on other patients in an attempt to establish clinical improvement by decreasing the demands on the circulatory system. Our patient's problem is further complicated by the possibility of inducing more cardiac symptoms if the metabolic rate is increased by the administration of thyroid substance. On the other hand, some of her cardiac symptoms may be the result of hypothyroidism. The transient changes in the T-waves and RT intervals of Leads II and III seemingly give objective evidence of impaired coronary circulation.

On June 4, 1937, her basal metabolic determination was minus 36 per cent after having taken desiccated thyroid 30 mg (gr $\frac{1}{2}$) daily for three weeks. Upon resuming this medication, she felt improved. The dose was then increased to 60 mg (gr I) daily with subjective improvement, although the patient was still having some cardiac symptoms particularly at night. On September 2, 1937 there was apparently a decrease in her exercise tolerance, in that after 23 trips she asked to stop by reason of pain. This is comparable with Blumgart's⁴² experience with patients who developed myxedema after total thyroidectomy for angina pectoris. Relatively small doses of desiccated thyroid substance were sufficient to diminish the gains in exercise tolerance made through the operation.

Case History 2—Illustrating the effect of exercise on the electrocardiograms of a patient with a duodenal ulcer and coronary artery disease complicated by a marked anxiety neurosis

The patient, Mr. A. T., a 43 year old clothing designer, was referred by Dr. Ellis B. Soble and Dr. George R. Lavine for cardiovascular study.

The important points obtained from Dr. Soble's record follow. Since 1932 the patient had complained of substernal and epigastric pain. History taking had always been affected by his extreme suggestibility and tendency to phobias. The onset of symptoms was sudden, immediately following the death of a friend from heart disease. The discomfort occurred after eating, was relieved by eructation, and was not affected by exercise. Relief was sometimes obtained by an enema. His general physical examination was negative, and the blood pressure varied from 140 systolic and 80 diastolic to 160 systolic and 100 diastolic. Gastrointestinal roentgenological studies showed evidence of duodenal ulceration. Marked relief was obtained by the administration of a bland diet and alkali, although, for a short while, he continued to have some of the discomfort in his chest. He was free from precordial discomfort until November 1935, when it recurred for a short time with numbness of the left arm. Throughout this period, the patient had been difficult because of hysterical symptoms. He remained relatively well until July 1936, when there occurred a sudden attack of severe epigastric pain. A diagnosis of perforated ulcer was made and

confirmed by operation. A resection was done, and convalescence was uneventful. In January 1937, his only complaint was "heart ache." The patient was uncertain whether or not he obtained relief by nitroglycerine. It was because of the persistence of these symptoms that he was referred to us for further study.

An insight into the psychiatric background was given by Dr. Lavine who summarized his studies as follows. The patient has always been shy, seclusive, and self-conscious. In his earlier years he had been protected by an older brother. After the brother's death, he became fearful and developed "shaking spells." He was irritable, apprehensive, and had definite sexual disabilities. He also had a fear of developing insanity. Since the sudden death of his friend, the patient thought that he had heart disease.

We first saw him in May 1937, and at that time he described the occurrence one week before of a pain in his left shoulder, numbness of the left arm, a "heaviness" over the upper sternum, and a tightness in his throat. Partial relief was obtained by resting, but greater relief was experienced after drinking a glass of water. It was hard to get a clear appraisal of his symptoms because of his proneness to contradict himself.

Since his operation eight months before, he had been conscious of hyperesthesia of the left shoulder region. In the morning when stooping to pick up his shoes, he would note a "cramp" in his left shoulder. The symptom, however, might occur at any time by "thinking about it." It was also noted in the morning when walking 15 yards to his garage. Bending to enter the car would increase the pain near the distal end of his left clavicle. It would radiate to the suprasternal notch and interscapular region and would last for 15 minutes. It was unaffected by breathing and was partially relieved by eructation or taking soda bicarbonate. The patient was not certain that nitroglycerine gave any relief, nor was he certain that he could produce the symptom by walking any other time of the day. He had been able to continue his daily work and apparently had very little difficulty except for the short period after breakfast.

His physical examination was essentially negative. The blood pressure was 146 systolic and 80 diastolic. The carotid sinus reflex was very active. Fluoroscopic examination of the chest was negative.

A single resting electrocardiogram, taken on May 8, 1937, showed very little change from the normal. The patient had experienced a severe pain two hours before the tracing was taken. T_1 was slightly diphasic, but it would be difficult to rule out the presence of a U-wave. The slight depression of RT_2 would not be given much significance by most clinicians. The presence of the diphasic T-wave in the chest lead is a possible deviation from the accepted normal.

Edekin, Wolferth and Wood⁴⁰ offer evidence that a diphasic T-wave in the chest lead or an upright T-wave in this lead are suggestive of heart disease. However, because many patients showing such borderline changes in their electrocardiograms are free from symptoms of cardiac disease and because of the extraordinary combination of gastrointestinal, cardiovascular, and mental symptoms in one patient, we felt it important to obtain as much objective evidence as possible.

It was with this in mind that we determined to study the effect of exercise. On June 5, 1937, two hours after a very light lunch and one and three-quarter hours after resting in recumbency, his basal electrocardiogram (A) was taken following which he was exercised at the rate of 12 excursions per minute.

| Elapsed time in minutes | No of trips | Remarks |
|-------------------------|-------------|---------------------------------------|
| 0 | 27 | "A little pain" |
| | 34 | (Pointing to left shoulder) "not bad" |
| | 43 | "Getting worse" |
| 3 45 | 44 | Exercise stopped |

The electrocardiograms taken before exercise (figure 2) on June 5, 1937, showed no deviation from the normal in the standard three leads. However, T_6 was diphasic. Electrocardiogram B started 75 seconds after the cessation of exercise, showed a drop in voltage of T_1 , a depression of RT_2 and RT_3 , and a change of T_2 and T_3 from positive to diphasic waves. The

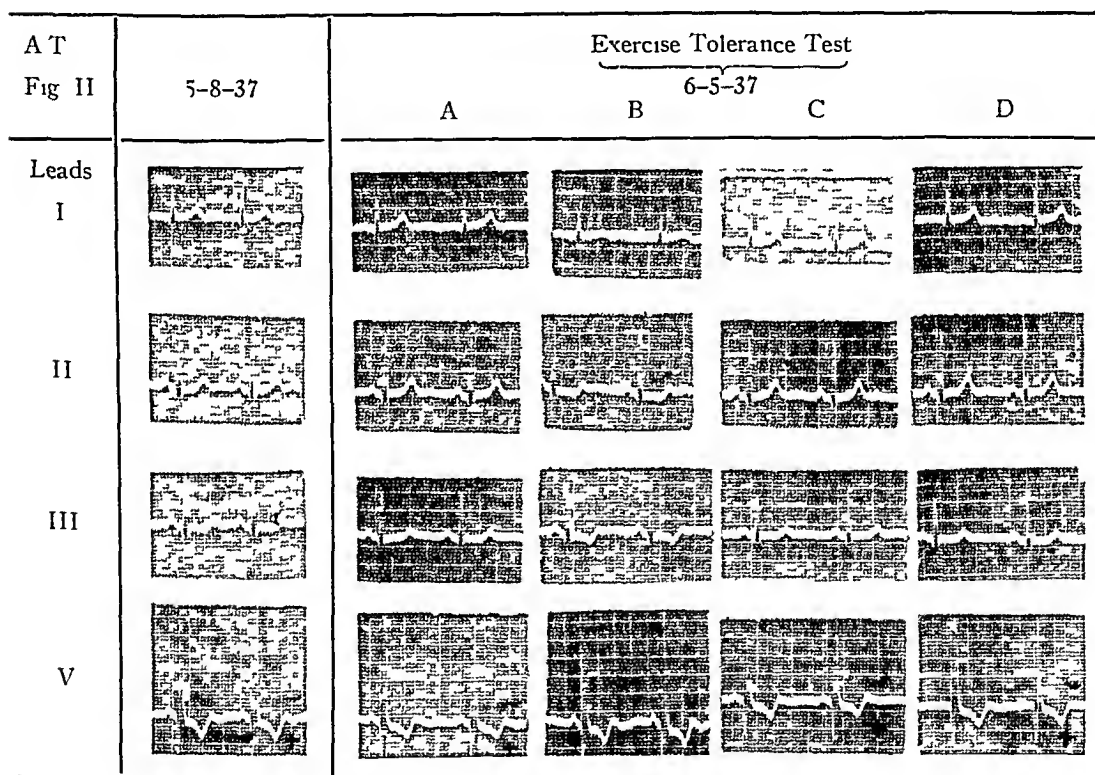

FIG 2 Electrocardiogram of Patient A T

May 8, 1937 Rate, 72 Slight depression of RT . T_1 is slightly diphasic. Patient had severe spontaneous attack of pain two hours before this electrocardiogram was taken. The chest lead shows a diphasic T-wave.

June 5 1937 Exercise tolerance test shows

A Resting electrocardiogram shows normal three conventional leads and diphasic T_3 . Rate is 65.

B Electrocardiogram taken 75 seconds after exercise. Rate is 60. T_1 has dropped and is slightly diphasic. T_2 and T_3 have become diphasic and are associated with a drop of the RT interval. The chest lead remains unchanged.

C Electrocardiogram taken 10 minutes and 15 seconds after exercise. The tracing has almost returned to A above. Rate is 58. T_1 is still slightly lower than T_1 in A.

D Electrocardiogram taken 16 minutes after exercise shows no change from A.

chest lead showed no significant change from the resting one. In electrocardiogram C, started 10 minutes and 15 seconds after the cessation of exercise, one notes almost a return to the resting electrocardiogram. T₁ is still a little lower than in electrocardiogram A. Electrocardiogram D, taken 16 minutes and 15 seconds after the cessation of exercise, duplicates the resting electrocardiogram.

The transient changes in the standard leads taken immediately after exercise would seem to give objective evidence of "myocardial ischemia."

Case History 3—Showing the effect of exercise on the electrocardiogram of a diabetic with symptoms of coronary disease. A routine electrocardiogram was essentially negative, the exercise test showed changes most marked in the chest lead.

Mr. E. C., a 46 year old tailor, was first seen on August 15, 1936, because of "back pain" and a "tight feeling" in his chest if he walked one block. His symptoms started gradually three years before. However, following the discovery of diabetes mellitus in 1934 and its control by diet, he felt well until four months before his first visit to our office. At that time, while ascending a flight of stairs, he experienced a sudden pain in his left scapula. Because this persisted for 24 hours he visited a physician, who bled and massaged his back. The pain was also noted over the front of his chest, more on the left than right side. He continued to work, although throughout that week he had the same discomfort every morning after ascending one flight of stairs, or if he walked more than one block. The discomfort would start in both scapulae, radiate over the top of the two shoulders to the left breast, and then to the right breast. At such times he became dyspneic and had to stop. His diabetes has remained under control by dietary means alone.

Physical examination showed his weight to be 171 pounds. Height was 5' 2½". Blood pressure was 132/80. The peripheral and retinal vessels were normal. Heart sounds were distant and the rate was 80. The heart was otherwise negative. Rhythm was regular. Moderate emphysema of the lungs was present. The abdomen was negative.

Laboratory tests showed the following: Blood sugar (mid-afternoon) three hours after a meal was 112 mg per cent. Blood Wassermann and Kahn tests were negative. Hemoglobin was 97 per cent. Red blood count was 5,500,000. White count was 5,800.

His exercise tolerance tests indicating the number of trips required to produce pain are shown in the table on page 2031.

It has been the experience of others (Riseman and Stern) that within limits the exercise tolerance is quite constant, and this was confirmed by our experience with a smaller series. Also, Brown and Riseman¹¹ have shown that an increase in exercise tolerance of 50 per cent or more usually caused a striking diminution or complete absence of attacks in daily life. Our protocol confirms the increase in exercise tolerance commented upon by Riseman and Brown in one of their recent papers¹² in which they described the beneficial effects of nitroglycerine and also xanthine derivatives on many of their angina pectoris patients. We heartily agree with their statement, "If medication induces improvement in a patient who has attacks on exertion, this improvement should be evidenced by an ability to perform more work than was possible without medication." In the protocol above on 11-20-37, it seems quite conclusively shown that for all practical purposes the effect of

Exercise Tests

| Date | Remarks | No. of Trips† to Produce Pain |
|----------|--|-------------------------------|
| 9-11-36 | Phyllicin* started | 19 |

† Theobromine—Calcium Salicylate

‡ Rate 12 to 14 trips per minute

nitroglycerine had ceased before the first exercise test was performed, and that following its administration the exercise tolerance increased by almost 120 per cent

The changes in the electrocardiograms (see figures 3 A and B) are reflected chiefly in the chest Lead (V). We have not encountered in any of our normal controls after exercise the change from the normally inverted T-wave in the chest lead to one that is diphasic, preponderantly positive, and associated with an elevation of the RT interval above the iso-electric line as demonstrated in this patient

On the basis of this patient's symptoms and the transient changes in his chest lead after exercise, we made a diagnosis of coronary disease. We suggest that such changes in the chest lead after exercise may be considered evidence of myocardial ischemia, even though the conventional three leads remain normal

DISCUSSION AND CONCLUSIONS

The earliest use of the electrocardiograph was directed to the analysis of abnormalities of rhythm and rate. As experience was gained it was found that valuable information about myocardial function was obtainable from a study of the shape, amplitude and time relations of the individual deflections. In more recent years the use of chest leads has frequently supplied information not obtained from the conventional three leads. However in many

patients with definite impairment of myocardial circulation, all routine clinical tests may yield negative results

Methods are discussed for obtaining objective evidence of myocardial ischemia (angina pectoris)—where the diagnosis would otherwise rest solely upon a more or less ambiguous history—by comparing electrocardiographic tracings, after rest, immediately after a measured amount of exercise, and at successive intervals after the exercise, using chest leads as well as the conventional three leads. We have been able to confirm the significance of the transient changes in the T-waves and RT segments described by other workers³⁻⁵. Particular importance is attached to including

FIG 3-A Electrocardiogram of Patient E C

August 18, 1936 Resting electrocardiogram Rate 58 Normal T-waves and RT intervals Slurring and notching of QRS in all leads Left axis deviation Deep Q.

September 11 1936 Exercise test shows

A Resting electrocardiogram which is almost identical with the one taken on August 18, 1936 T_s reaches but 3.5 mm below the iso-electric line in contrast with 6.5 mm below the iso-electric line in the tracing of August 18, 1936 This difference in the T-wave may be the result of a change in position of the chest electrode The rate is 53

B Electrocardiogram taken immediately after 19 trips on the standard steps Rate 50 RT_1 and RT_2 are slightly lower and T_1 and T_2 have dropped slightly in voltage In Lead V there is seen a distinct change in direction of the T-wave which is now upright and associated with a high take off of the RT interval The chest electrode was placed in the identical area as in electrocardiogram A

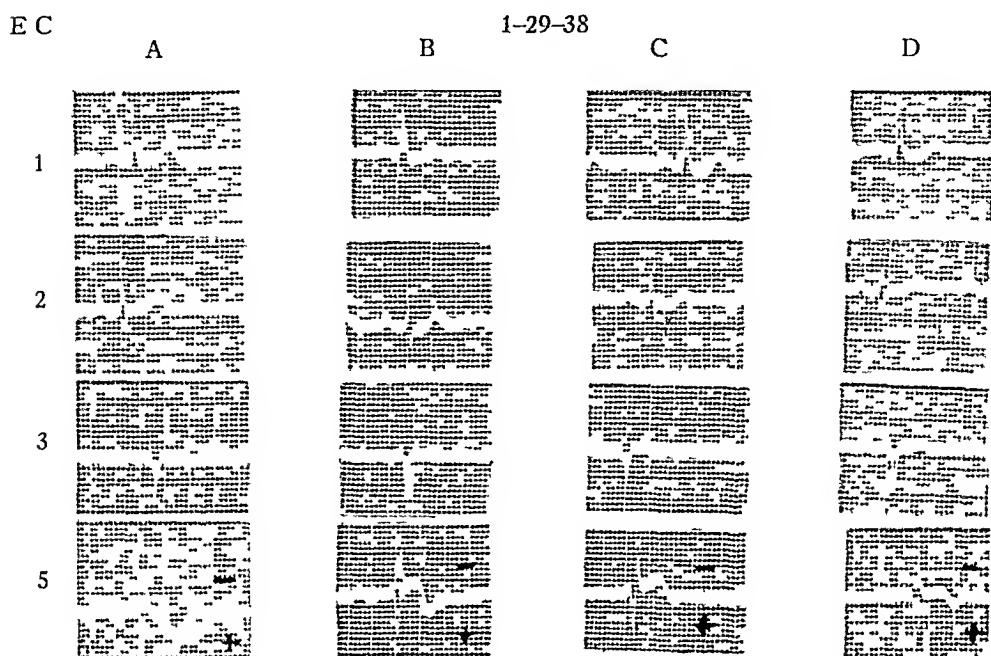

FIG 3-B Electrocardiograms of Patient E C, January 29, 1938

- A* Resting electrocardiogram Nitroglycerin $6\frac{1}{2}$ hours before No significant change from resting electrocardiograms on August 16, 1936 and September 11, 1936 Rate, 52
- B* Electrocardiogram after 36 trips Finished two minutes after cessation of exercise Rate 85-62 Observe negative shift of RT-1 and 2 and upward (negative) shift of the RT interval in the chest lead with a change in direction of T
- C* Started two and one-half minutes after *B* and finished in 85 seconds Rate, 65 Changes still persist in Leads I and II and are slightly less distinct in the chest lead
- D* Started two minutes after *C* (seven minutes after exercise ceased) and completed 75 seconds later Rate, 62 Shows less marked changes in Leads I, II, and V

the chest leads, since they sometimes yield positive information after exercise when the conventional three leads are negative. We have not encountered in any of our normal controls after exercise the change from the normally inverted T-wave in the chest lead to a diphasic or upright one with elevation of the RT interval nor have we noted the disappearance of the Q-wave in the chest lead after exercise. We believe that these changes may be considered objective evidence of myocardial ischemia. Electrocardiographic changes may occur after exercise even in the absence of pain production. (See Case History 1)

It is *not* to be assumed that negative results after the application of these tests disprove the existence of angina pectoris in the face of a history indicating its possible presence. At the present time it cannot be said that the tests have negative significance.

The tests are deprived of value unless the basal electrocardiogram is taken after adequate rest. Otherwise the contrast between rest and exercise is upset and the exercise administered is cumulative and incapable of

being accurately measured. At best there is only an approach to precision. For that matter, adequate rest is equally important before taking a routine electrocardiogram. The mechanism of individual cardiac attacks deserves study by this method also because in certain subjects these attacks may be the result of arrhythmias which, if recognized, may respond to appropriate therapy.

The history of the patient often indicates the approximate amount of exercise that can be tolerated. The work performed was measured on the "Standard Two-Steps," a method sufficiently simple and accurate to lend itself to clinical application. Such determinations may, of course, be made without observing the effect on the electrocardiogram. The methods used afford a possible means of observing the effect of therapy or the course of the morbid condition itself, inasmuch as a series of tracings, before and after exercise, may show changes where a series of tracings taken at rest do not.

In interpreting the tracings, it must be borne in mind that the mere fact that some changes appear does not necessarily indicate abnormality, since certain changes occur in normal subjects.

The coincidence of transient changes in the electrocardiogram with symptoms may in the selected atypical case establish a diagnosis otherwise uncertain (see Case History 2).

This method has proved entirely safe when the patient was admonished to stop on feeling any appreciable discomfort. Furthermore, in the hands of others, even when the exercise is carried to the point of causing pain severe enough to stop further activity, there have been no untoward results.

We wish to express our sincere thanks to Mr. Arthur E. Rosenberg for his assistance.

CASE REPORTS

A CASE OF CHRONIC HEMORRHAGIC BRIGHT'S DISEASE ASSOCIATED WITH AN ANOMALOUS BASOPHILIC PITUITARY GLAND*

By RAYMOND F. HOLDEN, JR., *New York, N. Y.*

IT is the purpose of this report to present a case of chronic hemorrhagic Bright's disease in which a remarkable pituitary basophilism apparently contributed to the clinical picture.

F. B., an unmarried Jewess of 30 years, referred by Drs. J. Eidelsberg and J. W. Wilner of New York City, entered the Rockefeller Institute Hospital May 11, 1935, with complaints of swelling of the face and lower extremities, increasing weakness, and failing vision for one and one-half years, also obesity and diabetes for 10 years.

Family and Personal History. The patient was one of a family of four children, her three sisters were healthy. Her family history was notable in that both grandmothers had diabetes, her mother had suffered from nephrolithiasis for 13 years, while her father, a mild diabetic, was at the time confined to bed by a hemiplegia.

Her health, up until 10 years before admission, had been fair. She had measles, scarlet fever, and diphtheria during childhood without obvious sequelae. A marked myopia had been present since infancy. She had been classed as mentally retarded in school and did not finish the eighth grade. Her occupations had included millinery, clerical, and household work.

The onset of catamenia was at 13 years. Menstruation had been normal until the past two years when it had become scanty and irregular.

About 10 years ago she had suddenly grown excessively fat. Shortly after this, a diagnosis of diabetes had been made. She had followed dietary restrictions in desultory fashion and during recent months had taken from 10 to 20 units of insulin daily.

Present Illness. Edema appeared first in November 1933, following a cold. During the following six months she gained 20 pounds in weight. She entered the Post-Graduate Hospital in November 1934. A diagnosis of chronic nephritis was made and a high-protein, low-salt diet was prescribed. Her weight fell from 200 to 159 pounds during her three weeks' stay in the hospital. On discharge she was instructed to continue the diet and 20 units of insulin daily for the diabetes. Thyroid was administered for a short time, but it produced severe muscular cramps and had no effect on the edema. She neglected her diet and began to gain weight again, so that she weighed 198 pounds on admission to The Rockefeller Hospital.

Physical Examination. The patient was an obese young woman with generalized anasarca. Her face was so swollen that the palpebral fissures were closed, while her lower extremities exhibited massive edema. The skin of her neck hung in folds and the breasts were extraordinarily large and pendulous. Aside from the dependent edema her appearance was rather similar to the photograph of Case 2 in Cushing's series (Cushing (1932), p. 151). There was a myopia of 10 + D, which made examination of the fundi difficult. Retinal arteriosclerosis, scattered hemorrhages, and deposits of exudate were noted. There was a pronounced upper dorsal

From the Hospital of The Rockefeller Institute for Medical Research, New York.

kyphosis. Moist rales were heard at both lung bases. The heart was not enlarged by percussion, but the aortic second sound was accentuated and the blood pressure was 224 mm Hg systolic and 116 diastolic. There were no signs of fluid in the large, flabby abdomen. The liver and spleen were not felt. Pelvic examination revealed a nulliparous cervix with a small amount of mucopurulent discharge, the fundus and ovaries could not be felt. The reflexes were sluggish.

Laboratory Data Roentgenograms of the heart and lungs demonstrated a relatively small thoracic cage, but no other abnormality. Lateral views of the skull showed a normal appearance of the sella turcica and cranial vault. Electrocardiograms indicated a normal cardiac mechanism with left axis deviation. The basal metabolic rate was plus 20 per cent, presumably due to thyroid taken before admission.

In addition to the data given in the graphic chart, the following laboratory findings were obtained: Blood non-protein nitrogen, 59 mg per cent, plasma free cholesterol 110 mg per cent, total cholesterol, 264 mg per cent, fasting blood sugar 65 mg per cent. After 100 gm glucose were taken by mouth the per cent blood sugar values were as follows: 1 hour, 112 mg, 2 hours, 138 mg, 3 hours, 99 mg.

Urine from the second half of a 24-hour Addis concentration test showed: Volume 950 cc, pH 7.0, specific gravity 1.0165 (corrected for protein), protein 7.9 grams per liter (7.5 grams per 12 hours), red blood cells 2.5 million in 12 hours, casts 140,000 (100 per cent hyaline), oval fat bodies. Subsequent laboratory findings are shown graphically in figure 1.

Clinical Course On the basis of the physical and laboratory findings, a diagnosis of chronic hemorrhagic Bright's disease was made. Single urine specimens showed persistent moderate glycosuria, not affected by administration of insulin, which was soon discontinued. Because of the peculiar obesity, high sugar tolerance, renal glycosuria, and menstrual irregularity a diagnosis of adiposogenital dystrophy was considered. The basal metabolic rate went to plus 43 per cent on a short course of thyroid, and the patient showed no improvement. She complained of constant pain in her thighs, also severe headaches. The blood pressure remained high and fresh retinal hemorrhages appeared. She lost weight (edema) rapidly on a high-protein diet with restricted salt, going from 90 kg on admission to 70 kg on discharge six weeks later.

After leaving the hospital she allowed her diet to lapse and began to grow edematous again. At the time of her second admission, three months later, she weighed 94 kg and appeared in every way the same as when she was first seen. The urea clearance was 12.5 per cent and the blood non-protein nitrogen 73 mg per cent. On the same diet given previously, her weight fell to 88 kg during three weeks in the hospital and she was again sent home. Edema returned promptly and she was readmitted a month later in an extremely weakened condition, despite efforts which had been made to provide a proper diet at home. The urea clearance was now 5.6 per cent and the blood non-protein nitrogen 102 mg per cent. At this time there were definite signs of fluid in her chest. She was again placed on a high-protein, low-salt diet and began to lose weight slowly. Increasing dyspnea and orthopnea set in and it was felt that cardiac decompensation had become a factor. Digitalis was given without any noteworthy effect. She complained of lower abdominal pain and had some vicarious menstruation. Nothing abnormal was noted on pelvic examination. During the following month signs of uremia supervened and she began to vomit with increasing frequency. The urea clearance fell to 2.5 per cent six weeks before death and remained at this level. She suffered a severe attack of secondary glaucoma and her vision failed completely, despite intensive treatment with eserine. Her weight dropped continuously, reaching 66 kg a week before death. The last complication to appear was a swelling of the right parotid gland, associated with cellulitis of the face and neck.

Autopsy The autopsy was carried out by Dr C P Rhoads, and the following data are from his record

A remarkable picture was presented by the pituitary gland and its environs (figures 2 and 3) The carotid bulbs extended to above the normal height and approached the midline to such an extent as to compress the hypophysis between them, so that its sides were concave and the antero-posterior diameter extended The vessels were soft and elastic, without aneurysmal change Microscopically, the anterior lobe was found to consist almost entirely of basophilic cells, with only a few groups of acidophilic cells The posterior lobe contained no adenoma and was not otherwise remarkable The kidneys were normal in size, shape, and consistency

FIG 2 Photograph showing a dorsal view of the pituitary in the sella turcica The carotid bulb can be seen on each side of the gland, somewhat separated from it for photographic purposes The lateral compression and deformity of the gland are well shown

The capsules stripped easily, leaving mottled brown-yellow surfaces which were slightly irregular The cortex was of normal thickness on section, but had a peculiar translucent appearance and presented scattered small yellow areas Many branches of the renal arteries were almost occluded by masses of atheromatous tissue The pelvis and ureters were not remarkable Microscopically, a very advanced chronic glomerulonephritis was apparent Hyaline deposits and endothelial proliferation within the glomeruli were present in various stages of development Fibrin thrombi were seen in some glomerular capillaries The tubules were dilated and showed widespread degeneration of the tubular epithelium The interstitial tissue was increased in amount and infiltrated with lymphocytes Intimal proliferation and atherosclerosis of the arteries were striking The left ventricle of the heart was

hypertrophied. Atheromatous areas were noted in most of the large arteries, especially in the renal arteries and their branches, the coronary arteries, and the circle of Willis. There were a few fibrous pleural adhesions and the lungs were moist, with frothy fluid in the bronchioles. The liver, spleen, and two accessory spleens appeared normal grossly. They showed some congestion on microscopic examination and there was much fat in the liver cells. The gastrointestinal tract, gall-bladder, and pancreas were normal. Both adrenals were grossly normal, while microscopically there was an excess of fat in the cortical cells. The uterus was small and the ovaries appeared normal, each containing corpora lutea. Multiple sections of the brain disclosed no abnormality.

FIG. 3. Top photograph showing a lateral view of the pituitary after removal from the sella. The flattened lateral surfaces are well shown.

Bottom photograph shows the cut surface of the pituitary after sagittal section.

DISCUSSION

It seems reasonable to suppose that the anatomical defect of the hypophysis antedated the nephritis, since there was no evidence of recent change in the position of the internal carotid arteries. Search of the recent literature has not produced any mention of similar defects*. If this anomaly is a rare one, as seems probable, then its presence in a case of nephritis would appear to be merely a coincidence. From the standpoint of clinical diagnosis, the presence of a gross deformity of the pituitary gland which could not be detected by lateral

* In a personal communication to Dr Rhoads, Dr Cushing stated that he had never seen an anomaly of this type.

stereoscopic radiograms of the skull seems significant. While it is recognized that roentgen-ray diagnosis of a normal sella turcica does not necessarily exclude gross defects of the hypophysis, nevertheless the anomaly in this case occasioned considerable surprise at the autopsy table.

The basophilic hyperplasia found in the anterior lobe may have been a result of injury by the lateral compression. From their frequent occurrence in the clinical syndrome of pituitary basophilia, it appears that the obesity, glycosuria, and menstrual irregularity were resultant effects of the hyperplasia. The duration of these symptoms would suggest that the basophilic condition was present for some time before the onset of nephritis. The possible causal relationship between pituitary basophilism and renal disease has been discussed fully by Cushing (1932, 1934) and by MacMahon, Close, and Hass (1934). Cushing (1934) states that "It has been pointed out separately by Erdheim, Tolken, Kraus, and Berblinger that an increase of basophilic elements in the glands as a whole is an accompaniment of advancing years of life when naturally enough it is often associated with atherosclerosis and renal disease." Nevertheless there has been a high incidence of nephritis among the cases of basophile adenoma in young adults which have been reported since the clinical syndrome of pituitary basophilism was described by Cushing (1932). In Cushing's original series, five out of eight patients who came to autopsy presented chronic nephritis of some degree. The cases reported by MacMahon, Close, and Hass (1934), Russell, Evans, and Crooke (1935), and Close (1935) all exhibited renal damage in varying amount. Those of Pardee (1934) and Hildebrand (1935) were apparently normal in this respect, although Pardee made little mention of urinary findings. Cushing (1932) suggested that the nephritis in his cases was probably secondary to the hypertension. However, just as in malignant hypertension, there is no *a priori* reason to assume that the nephritis may not come to dominate the picture. In the present case, it is not known whether hypertension antedated the onset of nephritis. Since the pituitary symptoms were present at an earlier date and since the pituitary at autopsy showed no evidence of recent change, it may be supposed with some certainty that the basophilic hyperplasia was present before the nephritis.

The course of the patient's (clinical) condition, and of the renal, blood and circulatory pictures, were quite similar to those observed in typical progressive chronic nephritis, without the pituitary element. The onset was insidious and the disease progressed in a little over two years to a fatal outcome, in accordance with the clinical dictum that gradual onset lends a bad prognosis in hemorrhagic nephritis. Good nutrition was maintained on a high-protein, low-salt diet* until a few weeks before death. Despite the high protein intake, which included supplements of casein up to 30 grams daily, the plasma protein remained low, and the deficit was entirely in the albumin fraction. The excretion of urinary protein averaged about 10 grams daily. The effect of low salt intake showed itself promptly in loss of edema fluid on each admission. Anemia was rather marked, so that the hemoglobin values averaged about 50 per cent of normal during the last five months of illness. Hematuria was never excessive. The blood pressure and cardiac hypertrophy were not unusual for nephritis. Most

* An effort was made to keep the protein intake up to 100 grams daily during the first admission. Because of the patient's capricious appetite, this was not accomplished with any regularity. Salt intake was kept below 1 gram daily.

of the characteristics summarized by Page † (1936) for a typical case of progressive nephritis were present in this patient

SUMMARY

1 A case of chronic hemorrhagic Bright's disease with clinical features suggestive of pituitary dystrophy is described. The clinical impression of hypophyseal disorder was confirmed by the postmortem finding of a grossly abnormal pituitary gland which contained a preponderance of basophilic elements.

2 The changes in renal function, circulatory system, edema, anemia, etc., were in degree and rate of progress, typical of an actively progressing nephritis. The pituitary anomaly had no obvious effect on the character or course of the nephritic syndrome.

COMPLETE AURICULOVENTRICULAR DISSOCIATION DUE TO DIGITALIS, WITHOUT SYSTEMIC EFFECTS OF OVERDOSAGE: REPORT OF A CASE*

By THOMAS J. DRY, M.B., and GILES A. KOELSCH, M.D.
Rochester, Minnesota

THE protean manifestations of digitalis intoxication, which consist of gastrointestinal disturbances, color vision phenomena and digitalis delirium, are well recognized. A group of electrocardiographic changes, including coupled beats, extrasystoles, ectopic rhythm, and conductive defects of varying degrees, is not infrequently encountered. It has long been known that changes in the T-wave (one variety of which is characteristic of digitalis poisoning) occur with great frequency and that they may be noted before any digestive disturbances have

† There was an excess of basophilic elements in the anterior hypophysis in this case also. Page (1936) did not find any clinical signs or symptoms suggestive of pituitary dysfunction in his case, however.

* Submitted for publication May 7, 1937.

occurred. It is doubtful, however, whether it is universally recognized that certain instances of gross overdigitalization, which are characterized by profound electrocardiographic changes, may not be associated with any of the usual systemic effects.

CASE REPORT

A woman, 39 years of age, who was rather high-strung and nervous, came to The Mayo Clinic in June 1936 complaining of palpitation on exertion or excitement. This had been present since she had been a girl. There was no history of rheumatic fever or of hypertension. She had gone through three pregnancies without incident, it had required an unusual amount of exertion to bring on breathlessness. There was no history of dependent edema, nor had she been subject to syncopal seizures. Because of the symptoms referable to her heart, one tablet of digitalis had been administered three times daily for about five weeks before her registration at the clinic and she had continued to take this dose until a few days before her first examination at the clinic.

For 10 years she had been troubled with epigastric bloating and fullness, which had not had any definite quantitative or qualitative relationship to the ingestion of food. During the few weeks prior to her visit to the clinic, these symptoms had, if anything, improved. There had not been any anorexia, nausea, vomiting, or disturbance of the bowels. Physical examination did not reveal any abnormality except an arrhythmia, the nature of which is disclosed by the electrocardiographic studies. The value for the systolic blood pressure was 110 millimeters of mercury and that for the diastolic was 64 millimeters. The pulse rate, when the patient was first seen, was 80 beats per minute. It was noted that pressure on the carotid sinus promptly caused a marked slowing of the pulse rate. There was not any enlargement of the heart or any bruits. The results of laboratory studies, including urinalysis, blood counts, roentgenographic studies of the heart and lungs, gall-bladder, and stomach, were all reported as normal. It was possible to keep the patient under observation for only a matter of 11 days. During this time, electrocardiographic studies, which were repeated on several days (figure 1a, b and c), revealed a gradual transition toward normal. Pressure over the carotid sinus caused very definite bradycardia, but as the digitalis effects wore off, it was no longer possible to elicit this phenomenon.

COMMENT

The absence of any probable basis for cardiac disease, the nature of the symptoms and their duration, the absence of the usual features associated with complete heart block, and the history of administration of relatively large doses of digitalis led us to suspect the true nature of the trouble. With our present incomplete knowledge of the carotid sinus reflex, we are unable to explain the peculiar electrocardiographic observations noted when pressure is applied over the carotid sinus, but we wish to record them as interesting findings.

It is frequently difficult to gauge the approximate amount of the drug administered in a given period of time from the history, and it is possible that certain patients have a heightened cardiac susceptibility to even small amounts of drugs which belong to the digitalis group. Yet, in the cases in which digitalis is clearly indicated, these changes, except perhaps for diphasic or inverted T-waves in the great majority of cases, fail to occur until clinical effects of overdosage become apparent.

Obviously, if an electrocardiographic record taken prior to the institution of digitalis therapy is not available under these circumstances, these changes

might be erroneously interpreted as indicative of severe myocardial damage, the result of organic heart disease. Moreover, should the patient present either clinical evidence of, or a background which may constitute the basis for, cardiac disease, the seriousness of that disease may be unnecessarily overestimated.

FIG 1a Electrocardiogram (June 18, 1936) showing complete auriculoventricular dissociation, the auricular rate is 106 and the ventricular rate is 70 per minute, one may note a short series of nodal premature contractions and inversion of the T-waves in Leads II and III, b, electrocardiogram (June 22, 1936) showing a rate of 80, nodal rhythm, periods of auriculoventricular dissociation, and a dropped beat, carotid pressure caused definite slowing of the heart, c, electrocardiogram (June 25, 1936) showing a rate of 65 sinus rhythm, sinoauricular block with upright T-waves in Leads I and II, and a diphasic T-wave in Lead III

Errors in diagnosis in these circumstances can be avoided if a sufficiently careful inquiry is made into the cardiac status of the patient prior to the institution of treatment. It is usually possible to ascertain whether there is any reason why organic heart disease might be present, such as the existence or history of hypertension, syphilis or coronary disease, including myocardial vascular accidents. Valvular lesions, both acquired and congenital, can be ascertained or ruled out by physical examination, again, one's suspicions should be aroused when the particular electrocardiographic pattern does not fit the pathologic picture (if any) presented by the patient.

This is well illustrated by the case of a woman, aged 42 years, who had a history of hypertension, but who had reasonably good tolerance to exertion. There was no cardiac enlargement and no history or evidence of congestive heart failure. She never had experienced pain which could in any way be labelled as anginal. The remarks noted at the time the patient was first seen were as follows: "The electrocardiographic changes are out of all proportion to the symptoms in spite of the hypertension." Furthermore, unless this patient had

FIG 2a Sinus rhythm with inversion of T-waves in Leads II and III, b, a normal electrocardiogram

had a previous myocardial infarct in the posterior basal part of the left ventricle (and we were sure that she had not, from the history), if any changes in the T-wave were present as a result of the hypertension, they should have been prominent in Leads I and II. Rheumatic heart disease with right ventricular strain might cause such changes in the electrocardiogram but this could readily be excluded by physical examination. After discontinuing all of her medications, one of which was digitalis, the electrocardiogram reverted completely to normal (figure 2a and b). It is important to remember also that the effects of digitalis on the electrocardiogram may persist for as long as three weeks after administration of the drug is discontinued.

Digitalis has its clear-cut indications in auricular fibrillation or as an adjunct to quinidine in auricular flutter, in certain cases of congestive heart failure, with or without an ectopic rhythm, and in certain instances in which the episodes of acute ventricular failure characterized by nocturnal dyspnea are not relieved by rest alone. The indiscriminate administration of an otherwise unequalled cardiac remedy for "all that ails" is to be strongly deprecated, particularly in those instances in which a frank discussion and a simple explanation of the mechanism of a variety of functional symptoms referable to the cardiovascular

system will suffice to reassure the patient and to relieve his mind as to any seriousness of their significance. Moreover, if digitalis therapy should be deemed necessary, the physician who prescribes this drug assumes the responsibility not only of administering it in amounts large enough to produce the desired pharmacologic effects, but also in amounts which shall not exceed the limits of physiologic safety.

SUMMARY

A case is reported in which too large a dosage of digitalis caused complete auriculoventricular dissociation. Despite profound electrocardiographic changes, systemic toxic effects were entirely absent. In this particular instance, the symptoms referable to the cardiac system were not the result of organic heart disease, and digitalis, far from being indicated in the management of the condition, might readily have led to confusion in its diagnosis and an unwarranted seriousness in the prognosis.

EDITORIAL

PROTAMINE INSULIN AND DIET IN DIABETES MELLITUS

BEFORE enumerating methods for achieving the best regulation of the diabetic regimen it is important to marshal the available facts that throw light on this phase of the disease. Only in this way can we clarify our objective and estimate the degree of success attained.

Adequate regulation of a patient with diabetes mellitus has been thought for a long time to consist in balancing the diet and insulin in a way that maintains the urine free from sugar, avoids periods of hyperglycemia, and at the same time avoids insulin reactions. In many patients this degree of regulation has not been possible and the ones who are difficult to regulate often vacillate precipitously from insulin shock to diabetic coma. With the use of protamine zinc insulin smooth adjustment occasionally is even more difficult and some of the more critical physicians who are especially interested in diabetes mellitus say that they have never seen a patient "regulated" on one daily dose of protamine insulin.

Some specialists in the treatment of diabetes advocate a high carbohydrate diet with one morning dose of protamine insulin which, in severe cases, may or may not be augmented by a simultaneous dose of regular insulin and they more or less ignore the presence of sugar in the urine up to as much as 40 gm. in 24 hours. It is obvious that such a regimen includes not only glycosuria but periods of marked hyperglycemia. Mosenthal¹ in 1935 expressed the belief that the damage done to the patient with diabetes mellitus occurred not from the abnormally high level of blood sugar but rather from the long continued effects of glycosuria with its attendant polyuria. In considering Mosenthal's hypothesis we can say in the first place that patients with renal glycosuria may excrete large quantities of sugar in the urine over periods of years without any evidence of damage resulting therefrom except undernutrition. This fact justifies some doubt as to the correctness of Mosenthal's principle. There is still the possibility that polyuria in a patient with true diabetes is more serious than in one with merely a low renal threshold for glucose but convincing evidence is lacking. In the second place there is fresh evidence to suggest that a patient whose urine is sugar free and whose blood sugar is constantly within normal limits may still not be properly regulated if the depots of glycogen, particularly in the liver, are not maintained at a normal level. It is clearly shown by de Wesselow and Griffiths² that it is impossible to classify patients as permanently insulin sensitive or insulin resistant. Patients who are insulin resistant become sensitive to insulin by carefully balancing a high carbohydrate intake.

with adequate doses of insulin. Bridge⁴ has come to the same conclusions from his studies on the action of insulin on glycogen reserves. He found in rabbits that large doses of insulin given during the course of glucose infusion serve to deposit more glycogen in the muscle and less in the liver but do not result in increasing the respiratory quotient. He has also found that after a poorly regulated patient with diabetes mellitus has been on a controlled high carbohydrate regimen for some time the respiratory quotient does become higher. Bridge, like de Wesselow and Griffiths, believes that this is brought about by an increase in the amount of hepatic glycogen and an improvement of glycogen metabolism in the liver. These findings are in accord with the statements of many clinicians that their patients are very much better while on a high carbohydrate diet.

It is impossible to say at present whether hyperglycemia and glycosuria are harmful if in other respects the sugar metabolism in the body is essentially normal. We can say, on the other hand, that severe insulin shocks and possibly repeated mild attacks of hypoglycemia are harmful and in the face of arteriosclerotic coronary or cerebral arteries are actually dangerous.

For the past decade several clinics both abroad and in this country have prescribed very high carbohydrate diets amounting to 300 or 400 gm of carbohydrate a day. Most clinics refuse to be quite so radical but practically all have been influenced to a greater or less extent. The general experience with diets containing between 150 and 225 gm of carbohydrates a day is that the patient feels better, likes his food better, needs little or no more insulin than on a lower diet and has fewer insulin reactions. It is interesting to find a rational explanation of these beneficial results in an improved hepatic glycogen metabolism with coincidental improvement in insulin utilization.

Protamine insulin introduces new problems of regulation. Since the absorption rate is so much slower than regular insulin the full effect from an injection is not obtained for five or six hours. After that the effect is more or less constant for the next 18 or 20 hours although the injected insulin is more rapidly utilized if food is taken than when it is not. Hypoglycemic reactions are usually encountered in the early morning hours after the long period of fasting during sleep. These facts necessitate certain changes in the dietary regime. Since the rate of absorption of protamine insulin is thought to be more uniform than the rate of production of endogenous insulin of a normal individual it is well to supply the carbohydrate in somewhat smaller amounts at shorter intervals. The indications may be met by starting the day with a small carbohydrate meal and by supplying some carbohydrate just before retiring at night. Another satisfactory formula for distributing the carbohydrate during the 24 hours is to divide

⁴ BRIDGE, E. M. The action of insulin on glycogen reserve, Bull Johns Hopkins Hosp, 1938, LXII, 408-421.

BRIDGE, E. M. and WINTER, E. A. Diabetes, carbohydrate combustion and insulin action, Bull Johns Hopkins Hosp (In press)

the total amount into $\frac{1}{6}$, $\frac{2}{6}$, $\frac{2}{6}$, for the three meals and then to subtract 10 gm from each meal and present it in a convenient form three hours after meals

If, then, one subscribes to the principle that the diet must contain enough carbohydrate to keep the hepatic storehouse of glycogen at a high level it is logical to place the lowest limit of carbohydrate in the diet at 150 gm a day. If the patient's caloric requirement permits, this amount may be increased to 200 gm or 225 gm daily. It is customary to keep the protein at the lowest level which is consistent with nitrogen balance and the fat low enough to prevent the patient from gaining weight or, if already overweight, to bring about a gradual loss of weight. Blood sugar estimations at intervals during the day and night often show normal variations when suitable protamine insulin dosage is given.

Unusual exercise is frequently followed by hypoglycemia. However, patients become familiar with this consequence of unusual exertion and learn to forestall severe attacks by eating extra bread or fruit or some other readily available carbohydrate. Where an amount of exercise customary to the patient is followed by a hypoglycemic reaction, reduction of the protamine insulin dosage is indicated but after the reduction glycosuria must be watched for more carefully than before.

Moderate variations in blood sugar levels are unimportant and extreme ones make themselves evident to the watchful patient in a way that enables him to change his single dose of insulin or his diet to suit the situation. It has been shown that excellent regulation with protamine insulin can be obtained by proper dietary adjustment of an adequately high carbohydrate intake. The patient not only is happier and feels very much better on this than on any other regimen but also the metabolic processes more nearly approach normal.

H M T, JR

REVIEWS

Protoformotherapy in Treatment and Prevention By N E ISCHLONDSKY 237 pages, 15 × 26 cm H Kimpton, London 1937 Price, \$5 00

The author has combined a series of lectures delivered before the Egyptian Medical Association of the University of Cairo into the above volume "Protoformotherapy," as defined, "is a basic conception, the most characteristic feature of which is the widest application of synthesis in the interpretation of morbid phenomena" The idea is based upon the supposed stimulation of the natural protective capacities of the organism by injection of an incret derived from embryos during the third and fourth month of gestation The incret is advocated by the author for the treatment of innumerable disease states pulmonary tuberculosis, chronic nephritis, endocrine disturbances and epileptiform states, constitute only a small number In support of the extraordinary results obtained in the treatment of these conditions, the author offers extremely inadequate case reports An inadequacy which in view of the monumental claims made by the author, throws great doubt upon the value of the work

J E B

In the Realm of Mind By CHARLES S MYERS, Psychologist 251 pages, 12 × 18 cm Cambridge University Press, London, Macmillan Co, New York 1938 Price, \$2 50

This book is made up of nine chapters on the applications and implications of psychology in the relationships of human society The fourth chapter will be of especial interest to medical readers as it is entitled "A Psychological Regard of Medical Education," and is a reprint of the Bradshaw Lecture, delivered before the Royal College of Physicians

The author feels that our present system of medical education tends to turn out specialists rather than clinicians because medical education is "almost wholly in the possession of specialists, each with his own vested interests, each maintaining the supreme importance of a full knowledge of his subject for the medical student, and strenuously opposing any reduction in the time devoted to it" He makes a plea that the future clinician should receive first a more general education in the whole range of medicine and surgery before he visits the "too water-tight departments of the specialist physicians and surgeons expressly to learn about the rarer diseases—but specialization should follow, not form part of, elementary medical education"

In the other chapters of this book the reader will find many thought provoking statements, and no doubt will agree with the author that "psychology unquestionably offers great help in the choice of a career"

J L McC

A Diabetic Manual By EDWARD L BORTZ, M D 222 pages, 14 × 20 5 cm F A Davis Co, Philadelphia 1936

Five authors have contributed to Dr Bortz's Manual for Diabetics There is an interesting foreword by Dr George Morris Piersol There is already a considerable number of manuals for diabetics available, but the present one presents many good features It is very readable and many of the sections are outstanding, for example those upon the "Administration of Insulin" and the "Care of the Feet" The chapter given up to the associated condition, obesity, is interesting and instructive

It appears as if the use and dangers of protamine-zinc-insulin were not given adequate discussion. It is questionable whether it is justifiable to say that "certain cases of renal glycosuria develop a mild form of diabetes in later years." There is some question also whether certain parts of the manual are not more suited for the comprehension of physicians than for that of patients.

J S E

A Textbook of Medicine Edited by RUSSELL L. CECIL, A B, M D, Sc D, Associate Editor for Diseases of the Nervous System, FOSTER KENNEDY, M D, F R S E. Fourth Edition, revised. 1614 pages, 17 × 25 cm. W B Saunders Co., Philadelphia. 1937. Price, \$9.00.

There can be no doubt that the new edition of this text will establish even more firmly its rapidly growing popularity. One hundred and forty authors have contributed to it, and the reader cannot but be impressed by the excellent editing and arrangement of the work—a difficult undertaking with such a large number of writers. The style is uniformly clear and concise and at the same time very readable and interesting.

Nine additional subjects have been introduced to the present volume. Twenty-nine subjects have been rewritten by authors new to the Textbook, partly because of the death of some of the former contributors, and partly because of a new editorial policy of retiring older writers and replacing their work by that of a younger group of teachers. The Editor, in his preface, regrets the loss of some of the articles, but his good judgment in selecting new contributors has made the present edition one of the best textbooks available, both for the student and practitioner.

COLLEGE NEWS NOTES

GIFTS TO THE COLLEGE LIBRARY

Grateful acknowledgment is made of the receipt of the following donations to the College Library

Books

- Dr F M Pottenger (Fellow and Regent), Monrovia, Calif—an autographed copy, Fifth Edition, "Symptoms of Visceral Disease",
Dr Emanuel M Josephson, New York, N Y—"Glaucoma and Its Medical Treatment with Cortin"

Reprints

- Dr George E Baker (Associate), Casper, Wyo—3 reprints,
Dr Karl F Eschelman (Fellow), Buffalo, N Y—1 reprint,
Dr James O Finney (Associate), Gadsden, Ala—3 reprints,
Dr William Freeman (Fellow), Worcester, Mass—1 reprint,
Dr Hyman I Goldstein (Associate), Camden, N J—2 reprints,
Dr Irving Gray (Fellow), Brooklyn, N Y—26 reprints,
Dr Jacob Gutman (Fellow), Brooklyn, N Y—Second Series Supplement to "The Modern Drug Encyclopedia",
Dr J Morrison Hutcheson (Fellow and Governor for Virginia), Richmond, Va—1 reprint,
Dr Vincent W Koch (Fellow), Janesville, Wis—1 reprint,
Dr Manfred Kraemer (Fellow), Newark, N J—2 reprints,
Dr Charles E Lyght (Associate), Northfield, Minn—4 reprints,
Dr Arthur M Master (Fellow), New York, N Y—20 reprints,
Dr William B Rawls (Fellow), New York, N Y—1 reprint,
Dr David Salkin (Associate), Hopemont, W Va—1 reprint,
Dr Benjamin Saslow (Associate), Newark, N J—1 reprint,
Dr Jacob Schwartz (Associate), Brooklyn, N Y—1 reprint,
Dr Christopher C Shaw (Associate), Bellows Falls, Vt—7 reprints,
Dr Frederick R Taylor (Fellow), High Point N C—Chapter VI-B and Chapter XIV-E, Oxford Loose-Leaf Medicine,
Dr Edward G Thorp (Fellow), Boston, Mass—5 reprints,
Dr Walter H Watterson (Fellow), La Grange, Ill—1 reprint
Dr Samuel Weiss (Fellow), New York, N Y—3 reprints
Dr M C Pincoffs (Fellow), Baltimore, Md, contributed a reprint by Dr Lewellys F Barker (Fellow), Baltimore, Md, on "Comments on Tetanus," the original article appearing in Volume I, No 4, February, 1921, of the "Annals of Medicine," the original official publication of the College

NEW LIFE MEMBERS

Dr Emanuel Klaus (Fellow), Cleveland, Ohio, and Dr Harry W Coffin (Fellow), Los Angeles, Calif, have become Life Members of the American College of Physicians making a total of one hundred and one members who have subscribed to Life Membership, four of whom are now deceased

MARYLAND CHAPTER OF THE COLLEGE

On April 19 Fellows of the College residing in Maryland held a meeting under the chairmanship of Dr Henry M Thomas, Jr (Fellow and Governor of the College for Maryland), at which it was decided to establish a so-called Maryland Chapter of the members of the College Dr Sydney R Miller (Fellow), Baltimore, was elected chairman for the first year It is planned to have at least two meetings a year and other meetings if special circumstances arise

Through arrangements by the American Heart Association, New York City, leading British and American physicians, 6,000 miles apart, conferred via the radio on Rheumatic Heart Disease, the greatest menace to child health This conference the first international broadcast on any health problem, was heard over the National Broadcasting Company, WEAf and the Red Network on May 2, in connection with the observance of National Child Health Day The conference was opened by Lord Thomas Jeeves Horder, Physician-in-ordinary to the King of England, from London Dr Homer F Swift of the Rockefeller Institute, New York City, and Dr T Duckett Jones of the House of the Good Samaritan, Boston, spoke from Atlantic City, where they were attending the convention of the American Society for Clinical Investigation Dr William J Kerr, President of the American College of Physicians and of the American Heart Association, took up the discussion from San Francisco

Under the Presidency of Dr Alphonse McMahon (Fellow), St Louis, the American Therapeutic Society held its Thirty-Ninth Annual Meeting at the Waldorf-Astoria Hotel in New York City April 1-2 1938 Among its officers were Dr Harold S Davidson (Fellow), Atlantic City, and Dr Hal McCluney Davison (Fellow), Atlanta, Ga, Vice Presidents, Dr Oscar B Hunter (Fellow), Washington, D C, Secretary, Dr Henry H Turner (Fellow), Oklahoma City, Treasurer On its Council of fifteen members all but four are Fellows of the College All but a very few of the Fellows and Active Members of this Society are Fellows of the College The majority of those presenting papers at the New York meeting were also Fellows of the College Dr F M Pottenger (Fellow and Regent), Monrovia, Calif, was a speaker of the evening at the annual dinner and President's Reception Dr Reynold Webb Wilcox, deceased, first president of the American College of Physicians, was the second president of the American Therapeutic Society

DR WILLIAM G HERRMAN RECEIVES RUTGERS AWARD

Dr William G Herrman (Fellow), Asbury Park N J, was the recipient of the Rutgers' Award, a medal of honor by Rutgers University for his outstanding service to society in the field of medicine, and for his loyalty to his Alma Mater, from which he graduated in 1912 The presentation was made on February 22, 1938, at a dinner celebrating the annual Alumni Day by the College The medal was presented by Dr Robert Clothier, President of the University

Citation

"Here, in the presence of your fellow-alumni, I want to pay the University's tribute to you for your services, both to your University and to your profession Voltaire wrote 'But nothing is more estimable than a physician who, having studied nature from his very youth, knows the properties of the human body,

the diseases which assail it, the remedies which will benefit it, exercises his art with caution and pays equal attention to the rich and poor' In war and in peace, you have practiced your profession with achievement and with promise of yet greater achievement to come, especially with reference to the application of radiology and roentgenology to medicine In recognition of your attainments, you have been made a Fellow of the American College of Physicians and of the American College of Radiology—and only recently the President of the Medical Society of New Jersey

"Yet, despite the exacting demands of your professional work, you have always found time to wear a trail back to the campus where you studied in those years prior to 1912 Your counsel and support have always been available to your Alma Mater It is appropriate that, with the authority of the Trustees, I should confer on you today the Rutgers University Award This medal, which I hand you, is the visible token of our tribute"

Dr Hilton S Read (Fellow), Atlantic City, is the chairman of the Welfare Committee (executive body) of the Medical Society of New Jersey

The Desert Sanatorium of Southern Arizona, located at Tucson, is conducting a special program and special low rates for arthritics from May 15 to October 15, 1938 The Sanatorium does not stress nor exploit any particular method of treatment of arthritis but, following out good medical practice, bases therapy upon the diagnostic findings in each case

Dr Roland Davison (Fellow) is the Medical Director and Dr C W Mills (Fellow) is the Chief Visiting Physician

Dr Joseph Hajek (Fellow) and Dr Thomas T Mackie (Fellow), both of New York City, were Chairman and Secretary, respectively, of the Section on Medicine of the New York Academy of Medicine for the year 1937-38

Dr Hajek contributed a paper on "The Cardiogram in Health and Disease" on the Scientific Program of the South Brooklyn Medical Society Meeting, April 14, 1938

Dr Ross M Lymburner (Fellow), Hamilton, Ontario, spoke on "The Treatment and Later Management of Coronary Thrombosis" before the annual meeting of the Ontario Medical Association, held at the Royal York Hotel, Toronto, Ontario, May 2 to 6

Dr H I Spector (Associate), St Louis, has received a joint invitation from the Kansas State Medical Society, Kansas State Board of Health and the Kansas Tuberculosis and Health Association to lecture to the medical societies of several cities of the State of Kansas on the subject of "Symptoms Diagnosis and Differential Diagnosis of Early Pulmonary Tuberculosis" He was the guest of the Leavenworth County Medical Society on April 18, of the Franklin County Medical Society in Ottawa on April 19, of the Sedgwick County Medical Society in Wichita on April 21, and of the Central Kansas Medical Society in Russell on April 22

On March 10, 1938, the Morgan County (Illinois) Medical Society held its Fiftieth Anniversary Celebration Meeting, honoring Dr Frank Parsons Norbury (Fellow), of Jacksonville, Ill. The speakers included Hon A L Bowen, Director of the Department of Public Welfare, State of Illinois, Dr Tom B Throckmorton (Fellow), Des Moines, Iowa, and Dr Charles L Patton, F A C S, Springfield, Ill

On February 8, 1938, members of the American College of Physicians in Puerto Rico gave a farewell dinner to Dr Ramon M Suarez, Governor of the College for Puerto Rico, preceding his sailing to participate in the postgraduate course offered under the auspices of the College at Harvard University. Among the Puerto Rico members present were Dr Ramon M Suarez, Dr Carlos E Muñoz MacCormick, Dr Guillermo Marques, Dr Antonio Ortiz, Dr Luis Morales, Dr Cesar Dominguez, Dr R Rodriguez-Molina, Dr Enrique Koppisch, Dr Jose Landron, Dr O Costa-Mandry and Dr Jose Garrido Collazo.

Dr Suarez later attended the Annual Session of the College at New York City, taking his place on the Board of Governors as the representative from Puerto Rico. On behalf of the Fellows and Associates of the College in Puerto Rico, Dr Suarez presented a set of resolutions signed by all the Puerto Rico members, inviting the College to come to Puerto Rico on a post-convention cruise to inspect their work and institutions.

Dr Warren F Kahle (Fellow), 17 N Chatsworth Avenue, Larchmont, N Y, has prepared a very interesting and instructive talking slide film on the subject, "Treating Pneumonia." This film has but recently been completed, and Dr Kahle has expressed his willingness to loan it to Fellows of the College. It requires twenty-three minutes, and is a combination of still and talking film. The apparatus for showing the film is available in practically every community. The film and the record may be loaned, or Dr Kahle will show it personally to groups not too far removed from Larchmont.

The Chicago Tumor Institute opened March 21, 1938, offering consultation service to physicians in the diagnosis and treatment of cancer and radiation facilities for cancer patients. The Institute also proposes to conduct research and to offer training to physicians who may wish to qualify as specialists in the study and treatment of this disease. The scientific committee consists of Max Cutler, M D, Director, Sir G Lenthal Cheatle, F R C S, Henri Coutard, M D, Arthur H Compton, Ph D and Ludwig Hektoen, M D.

Dr A A Leonidoff (Associate), Poughkeepsie, N Y, addressed the Dutchess County Psychiatric Society March 18, 1938, on "Control of Tuberculosis in the Hudson River State Hospital."

Dr Arthur J Logie (Associate), Jacksonville, Fla, addressed the Polk County Medical Society at Lakeland, Fla, on January 12, 1938, the Suwannee River Medical Society at Mayo, Fla, on February 11, 1938, the Florida Tuberculosis Association at Orlando, Fla, on April 26, 1938, and the Duval County Medical Society at Jacksonville, Fla on May 2, 1938. His subject was "The Value and Significance of the Tuberculin Test."

Dr M Coleman Harris (Fellow), New York City, has been advanced to Adjunct Professor of Medicine and Head of the Department of Allergy at the New York Polyclinic Hospital. Because of the added duties of this new appointment, he has resigned his appointment at Roosevelt Hospital

Under the presidency of Dr Edward S Sledge (Fellow) Mobile, the Medical Association of the State of Alabama held its annual meeting in Mobile, April 19-21. Among members of the College who contributed to the program were Dr John H Musser (Fellow), New Orleans, "Treatment of Organic and Inorganic Diseases of the Stomach", Dr Oscar W Bethea (Fellow), New Orleans, "The Pneumonias", and Dr Joe H Little (Associate), Mobile, "Progress in the Treatment of Diabetes"

Dr Thomas M McMillan (Fellow), Philadelphia, delivered the Jerome Cochran Lecture on "An Optimistic View of Some Problems of Heart Disease"

Dr Joseph Yampolsky (Fellow), Atlanta, Ga addressed the Thirteenth Annual Session of the Alabama Pediatric Society, April 18, on "A Comparative Review of the Drugs Used in the Treatment of Syphilis"

Dr Elliott P Joslin (Fellow), Boston, addressed the Chicago Medical Society April 6 on "Present Conceptions of Diabetes Mellitus"

Dr Alan Brown (Fellow), Toronto, Ont, addressed the Northern Tri-State Medical Association in Findlay, Ohio, April 12, on "Some Common Disturbances in Children Frequently Handled Incorrectly"

Dr M Herbert Barker (Associate), Chicago, addressed the Arkansas Medical Society at Texarkana April 18-20 on "Phases of Renal Edema and Their Treatment"

Dr Benjamin W Black (Fellow), Oakland and Dr Clifford W Mack (Fellow), Livermore, have been appointed to a committee to aid the California State interim committee on state hospitals, authorized by the legislature to study hospitalization of the insane

Dr Logan Clendenen (Fellow), Kansas City, Mo, delivered a public lecture on "The Care and Feeding of Humans" under the auspices of the Chicago Medical Society at the Goodman Theater in Chicago on April 13

Dr William Devitt (Fellow), Allenwood, Pa, was elected president of the Pennsylvania Tuberculosis Society

Dr Udo J Wile (Fellow) Ann Arbor, addressed the Allegheny County (Pa) Medical Society at Pittsburgh, April 19, on "Syphilis in Relation to Surgical Problems"

Dr John Zahorsky (Fellow), St Louis, addressed the one hundred and fifth annual meeting of the Tennessee State Medical Association at Nashville, April 12-14, on "The Newborn Baby in the Hospital"

Among guest speakers at the annual meeting of the Texas Tuberculosis Association held in El Paso, April 15-16, were Dr Jay Arthur Myers (Fellow), Minneapolis, president of the National Tuberculosis Association, and Dr Lewis J Moorman (Fellow), Oklahoma City

Dr James N Williams (Associate), Richmond, Va, addressed the sixty-second annual meeting of the American Association on Mental Deficiency at Richmond, April 20-23, on "Emotional Education of Children"

Stanford University School of Medicine, San Francisco, has inaugurated a course of popular medical lectures Among Fellows of the College who have recently contributed are Dr Walter W Boardman (Fellow), San Francisco, "Conditions of the Mouth in Relation to Disease", Dr William J Kerr (Fellow and President), San Francisco, "Forty, Fat and Florid and Heading for Circulatory Failure", and Dr Dwight L Wilbur (Fellow), San Francisco, "Vitamin Facts and Fallacies"

Dr James S McLester (Fellow), Birmingham, Ala, delivered the Ewing Fox Howard Oration on "Causes and Effects of Hypertension" before the seventy-first annual session of the Mississippi State Medical Association at Jackson, Miss, April 19-21

Under the presidency of Dr Homer Davis (Fellow), Genoa, Nebr, the Nebraska State Medical Association held its annual convention at Lincoln, April 26-28

Dr Arthur C Christie (Fellow), Washington, D C, delivered the annual J Chalmers DaCosta Foundation Lecture on "Comprehensive Planning for Medical Care—the Physician's Responsibility," March 30, before the third annual Post-graduate Institute of the Philadelphia County Medical Society Dr Rufus S Reeves (Fellow), Philadelphia, was chairman of the committee that organized the Institute

Dr Bernard L Wyatt (Fellow), Tucson, Ariz, was recently awarded a medal from the Comité National de Défense contre la Tuberculose in France in appreciation of his work in tuberculosis during the World War

Dr Robert A Hare (Fellow), Santa Barbara, Calif, was recently appointed Medical Director of the Washington Sanatorium and Hospital, Takoma Park, Washington, D C

Dr Thomas Parran (Fellow), Surgeon General of the U S Public Health Service, was recently awarded a medal by the "Parents Magazine" for outstanding service to children

Dr Cyrus C Sturgis (Fellow), Ann Arbor, addressed the eighty-seventh annual session of the Iowa State Medical Society at Des Moines, May 11-13, on "Diseases Associated with Changes in the Red Blood Cells"

Dr Ray M Balyeat (Fellow), Oklahoma City, addressed the Louisiana State Medical Society at New Orleans, May 2-4, on "Common Allergic Manifestations Encountered by the General Practitioner"

Dr Leonard G Rowntree (Fellow), Director of the Philadelphia Institute for Medical Research, was the recipient of the annual Strittmatter Award, a gold medal, at a meeting of the Philadelphia County Medical Society on April 13, the award being made in recognition of Dr Rowntree's work on the thymus gland, cancer and arthritis

Dr Eugene F DuBois (Fellow) and James D Hardy, New York, addressed the National Academy of Sciences at Washington, D C, recently on "Relationship of Humidity to Evaporation of Sweat"

Dr William R Houston (Fellow), Austin, Texas, was the banquet speaker at the forty-first annual meeting of the American Gastro-Enterological Association at Atlantic City, May 2-3, his subject being, "Our Relations with the Orient" Dr Houston also addressed the Medical Society of the District of Columbia at the public meeting in connection with its annual scientific assembly May 4-5 on "Western Medicine in China"

Dr Edward A Strecker (Fellow), Philadelphia, addressed the one hundred and thirty-second annual meeting of the Medical Society of the State of New York, held in New York City, May 9-12, on "The Importance of Psychology in the Practice of Medicine"

Dr Paul A O'Leary (Fellow), Rochester, Minn, addressed one of the sections on "Significance of Asymptomatic Neurosyphilis"

The eighty-fifth annual session of the Medical Society of the State of North Carolina was held at Pinehurst May 2-4, under the presidency of Dr Wingate M Johnson (Fellow), Winston-Salem

Among the guest speakers was Dr Edward A Strecker (Fellow), Philadelphia, "Functional Illness and the Medical Psychology Needed by the Practitioner in Its Treatment"

A memorial tablet to the late Dr William Duffield Robinson (Fellow), was unveiled by the trustees of the Philadelphia Institute for Medical Research at its building at the Philadelphia General Hospital on April 7 Dr Robinson was active in the formation of the Institute He died in 1931

Dr James B Collip (Fellow), Montreal, Que, addressed the Philadelphia Pediatric Society April 12 on "Anterior Pituitary Hormones"

Dr John A Kolmer (Fellow), Philadelphia, addressed the seventy-second annual session of the Texas State Medical Association at Galveston, May 10-12, on "Syphilis"

The Congress of American Physicians and Surgeons held its Semi-Centenary Meeting at Atlantic City, May 3-4, 1938, under the presidency of Dr James B Herrick (Fellow and 1st Vice President), Chicago. The Congress is held every five years. The component associations and societies include the American Otological Society, American Neurological Association, American Gynecological Society*, American Dermatological Association*, American Laryngological Association, American Surgical Association, American Clinical and Climatological Association, Association of American Physicians, American Association of Genito-Urinary Surgeons, American Orthopedic Association, American Pediatric Society*, American Association of Pathologists and Bacteriologists. However, those societies marked with an asterisk did not hold meetings with the Congress this year.

Among the officers of the Association of American Physicians were Dr George R Minot (Fellow), Boston, President, Dr Eugene F DuBois (Fellow), New York, Vice President, Dr Hugh J Morgan (Fellow), Nashville, Tenn, Secretary, Dr William S McCann (Fellow), Rochester, N Y, Treasurer, Dr Francis G Blake (Fellow and Governor), New Haven, Conn, Recorder, Dr Gerald B Webb (Fellow), Colorado Springs, Dr Louis Hamman (Fellow), Baltimore, Dr James H Means (Fellow and Ex-President), Boston, Dr George Blumer (Fellow), New Haven, Conn, and Dr Warfield T Longcope (Fellow), Baltimore, Members of the Council, Dr O H Perry Pepper (Fellow and President-Elect), Philadelphia, Delegate to the Executive Committee of the Congress, Dr Ernest E Ions (Fellow), Chicago, Alternate Delegate, Dr Richard A Kern (Fellow), Philadelphia, Alternate Committeeman.

Among the officers of the American Clinical and Climatological Association were Drs John H Musser (Fellow), New Orleans, and James J Waring (Fellow), Denver, Vice Presidents, Dr Francis M Rackemann (Fellow), Boston, Secretary and Treasurer, Drs J Burns Amberson, Jr (Fellow), New York, O H Perry Pepper (Fellow), Philadelphia, Henry M Thomas (Fellow and Governor), Baltimore, James E Paulin (Fellow), Atlanta and Chester S Keefer (Fellow), Boston, Members of the Council, Dr George Morris Piersol (Fellow), Philadelphia, Alternate Delegate to the Executive Committee of the Congress, Dr Richard A Kern (Fellow), Philadelphia, member of the Committee on Arrangements.

Among the officers of the American Association of Pathologists and Bacteriologists were Dr Earl B McKinley (Fellow), Washington, D C, Vice President, Dr Howard T Karsner (Fellow), Cleveland, Ohio, Secretary, Dr C V Weller (Fellow), Ann Arbor, Member of the Council, Lt Col George R Callander (Fellow), M C, U S A, Delegate to the Executive Committee of the Congress, Dr Ward J MacNeil (Fellow), New York, Alternate Delegate.

Dr Elmer L Sevringhaus (Fellow), Madison, Wis, was a guest speaker at the ninety-eighth annual meeting of the Illinois State Medical Society at Springfield, May 17-19, his subject being "Pituitary Therapy in General Practice"

Among the guest speakers at the one hundred and forty-seventh annual meeting of the New Hampshire Medical Society at Manchester May 17-18 were Dr Walter

Bauer (Fellow), Boston, "Treatment of Arthritis", Dr Donald S King (Fellow), Boston, "Cancer of the Lung", and Dr Frederick T Lord (Fellow), Boston, "Treatment of Pneumonia"

Among the guest speakers at the annual meeting of the Medical Society of New Jersey, held at Atlantic City, May 17-19, were Dr Josephine B Neal (Fellow), New York, "Treatment of Infections of the Central Nervous System with Special Reference to Sulfanilamide", and Dr George B Eusterman (Fellow), Rochester Minn, "Newer Aspects in Etiology and Treatment of Ulcers of the Gastrointestinal Tract"

Dr William S Rude (Fellow), Ridgely, was elected a vice-president of the Tennessee State Medical Association at its annual meeting in Nashville during April

OBITUARIES

DR LEWIS BURGİN McBRAYER

Lewis Burgin McBrayer died at his home in Southern Pines, N C, April 1, 1938. He was born in Buncombe County, December 27, 1868, and his long and useful career in medicine from the time of his graduation from the Louisville (Ky) Medical College in 1889 was spent within the confines of his native State. For twenty-five years he practiced in Asheville, serving as County Coroner of Buncombe County, and City Health Officer of Asheville, becoming, in 1914, the Superintendent of the North Carolina State Tuberculosis Sanatorium, at Sanatorium, N C.

He was President of the Buncombe County Medical Society about 1900. From 1915 to 1920 he was Secretary of the Hoke County Medical Society, in 1918-19, he was Chairman of the Section on Public Health of the Southern Medical Association, in 1919 he was President of the Moore County Medical Society, in 1925-26 he was President of the Southern Conference on Tuberculosis, he was Managing Director of the North Carolina Tuberculosis Association, and President of the North Carolina Medical Society, as well as a member and President one year of the State Board of Medical Examiners, after which he became Secretary-Treasurer of the State Medical Society, and from 1921 until his retirement two years ago, he was given the title of "Honorary Secretary for Life" of this Society.

Being keenly interested in the furtherance of organized medicine, he was always vitally interested in, and a member of, his local County Medical Society, State Medical Society, the Southern Medical Association, the American Medical Association, the National Tuberculosis Association and its regional subdivisions, and the American College of Physicians, of which he became a Fellow in 1920, maintaining an active interest in all of these associations until illness incapacitated him.

In 1890, Dr McBrayer married Miss Lillian Cordie Deaver, of Asheville, of which union three children survive. Mrs Paul P McCain, wife of Paul P McCain, M D, F A C P, present Superintendent of the North Carolina State Tuberculosis Sanatorium, Lewis B McBrayer, Jr, and Reuben A McBrayer.

Dr McBrayer was actively interested in the Order of Odd Fellows, which organization gave him some of its highest honors, he finally serving in 1933-34 as Grand Marshal of the sovereign grand lodge. His civic interests embraced the Sand Hill Fruit Growers Association, of which he was President in 1922, the Chamber of Commerce of Southern Pines, the United States No 1 Highway Association, both of which latter organizations he also served as President. Dr McBrayer's outstanding contribution to the medical life of his State was his vitalizing interest and campaigns for the betterment of public health, and for the prevention and eradication of

tuberculosis In the American College of Physicians, he was so far as known the initiator of the idea of sectional meetings, when in 1930 the President of the College, the Secretary-General and the Executive Secretary, on his invitation, were the guests of the Fellows of the State at a luncheon during the meeting of the State Society at Pinehurst

In Dr McBrayer's death, his community, State and the country at large, have lost an enthusiastic, tireless worker in the field of preventive medicine

C H COCKE, M D ,
Governor for North Carolina

DR STEPHEN WEBB DAVIS

Dr Stephen Webb Davis, of Charlotte, N C, who died suddenly on March 16, 1938, was born September 1, 1894, the son of the late Thomas Jackson Davis and of Ella Webb Davis Dr Davis graduated from the Virginia Polytechnic Institute with a B S degree, and received the degree of M D from the University of Pennsylvania, with honors, in 1927 He served as Resident Physician at the University Hospital, in Philadelphia, and pursued postgraduate studies at the Mayo Clinic, the Government Research Station, at Beaufort, N C, and other places Prior to entering medicine, Dr Davis served as First Lieutenant of the 11th Cavalry, U S Army, during the World War, being stationed in the West and on the Mexican border

He was a member of Sigma Chi and Phi Chi (medical) fraternities, of the Mecklenburg County Medical Society, the North Carolina State Medical Society, the Tri State Medical Society of the Carolinas and Virginia, the Southern Medical Association, a Fellow of the American Medical Association, member of the American Heart Association, and became a Fellow of the American College of Physicians in 1936 He belonged to the Rotary Club of Charlotte, and to the Westmoreland Club of Richmond

In June 1935, he married Miss Kate Jones, of Summerville, Ga, and leaves his wife and one daughter, born March 9, 1938

Dr Davis was largely interested in the progressive phases of Internal Medicine, developing, some years ago, an oxygen service, available to his colleagues, and lately was tremendously interested in peripheral vascular disease, equipping himself with all the modern instruments used in these conditions He was an earnest student, an interested and zealous physician, and attempted to keep himself in the forefront of progress in his chosen field

His sudden and unexpected death cut short what might well have been a very brilliant career in internal medicine

C H COCKE, M D ,
Governor for North Carolina

MINUTES OF THE GENERAL BUSINESS MEETING

NEW YORK, N Y , APRIL 7, 1938

The Annual Business Meeting of the American College of Physicians was held at the Waldorf-Astoria Hotel, New York City, April 7, 1938. The meeting was called to order at eleven-thirty o'clock by Dr. James H. Means, President.

Abstracted Minutes of the last Annual Business Meeting were read by the Executive Secretary, Mr. E. R. Loveland, which, upon motion duly seconded and carried, were accepted as read.

The Treasurer, Dr. William D. Stroud, reported that the finances of the College were in a satisfactory state, and that the accounts had been examined and found correct by a Certified Public Accountant. He reported that on December 31, 1937, the total assets of the College, according to book value, amounted to \$205,383.47, of which \$64,534.27 was in the Endowment Fund and \$140,849.20 was in the General Fund, \$63,308.98 represented the book value of investments in the Endowment Fund, the balance of the Fund being in cash. \$64,941.60, according to book value, of the General Fund was invested in securities, the balance being represented partly in cash (\$2,891.75), partly in the College Headquarters (\$57,582.45), and partly in other assets as will be disclosed in the detailed financial reports following these Minutes. The Treasurer further referred to the detailed statements which hereafter follow.

Upon motion duly seconded and carried, the report of the Treasurer was accepted. The Executive Secretary, Mr. E. R. Loveland, presented the following report:

"During the summer and early autumn of 1937, a completely new and revised Directory of the American College of Physicians was compiled and published. Under the direction and recommendations of the Board of Governors and the Board of Regents the form of the Directory was somewhat changed, making it more informative and more practical.

"An extension of the activities of the College included the organization of Postgraduate Courses, restricted to members, given during the two weeks preceding the Annual Session. Although the project was started rather late and the final bulletins of the courses distributed only a month in advance of the Annual Session, there were formally registered 55 student-physicians in Course No. 1, in 'General Medicine,' at Harvard University Medical School, 27 student-physicians for Course No. 5, in 'General Medicine,' at the New York Post-Graduate Medical School and Hospital, 25 student-physicians for Course No. 6 'Cardiovascular Diseases' at the University of Pennsylvania Graduate School of Medicine, and 13 student-physicians for Course No. 7 'Gastro-Intestinal Diseases' also at the University of Pennsylvania Graduate School of Medicine.

"The Committee on Postgraduate Education, provided for by the Board of Regents, and appointed by the President, will continue its survey of graduate educational facilities in this country, and will also prepare a program of graduate courses for members of the College, the courses to be given in centers in or near-by the next meeting city. Full information will be published at the appropriate time in the ANNALS OF INTERNAL MEDICINE.

"The Twenty-Second Annual Session of the College in New York City has marked a high spot in the entire list of the Sessions of the College. The President, the General Chairman, the Vice Chairman and the local Committees have done a tremendous amount of work, and given the meeting much thought, which has resulted in a program second to none. The success of the meeting is attested to by the enthusiastic reports of our members and by the largest member regis-

tration at any Annual Session. The general registration was 2,228, with 319 visiting ladies, making a total of 2,547. The Round Table Conferences proved tremendously popular, with the result that we were unable to accommodate a great many of the members desiring tickets. No other innovation in the annual program has proved so popular.

"The attention of members is particularly called to the very high type of our Technical Exhibits this year, and that the number of exhibits has been reduced. The exhibits are being restricted to those having a direct relation to Internal Medicine and its allied specialties, many irrelevant and miscellaneous commercial exhibits have been eliminated. It is felt that exhibitors should be present primarily to give information and service, and not especially to make direct sales. The College desires to make its Commercial Exhibits scientific in character, and to enhance their value to its members. The revenue from exhibits goes a long way toward paying the expenses of the Annual Sessions; therefore, we owe the exhibitors our courteous attention. Members are urged to visit the various booths, for the exhibitors will be appreciative of the fact that the College members are sufficiently interested to examine the displays on which they have spent so much time and expense in preparation.

"The College accounts, according to our universal custom, have been audited by a Certified Public Accountant, and all the statements have been presented and approved by the Finance Committee and the Board of Regents. Through the cooperation of the Treasurer and the Secretary-General, and the help of a competent staff, the work in the Executive Offices of the College has been carried on with as great dispatch, promptness and efficiency as possible.

"In conclusion, I want to remind you again that we are always happy to have members visit us at our Headquarters in Philadelphia. We are gratified that so many have come during the past year, and any service we can perform is considered a privilege."

By motion duly seconded and carried, the report of the Executive Secretary was approved.

The Secretary-General, Dr. George Morris Piersol, presented the following report:

"The total membership of the American College of Physicians at this date is approximately as follows:

| |
|------------------|
| 2 Masters |
| 2,820 Fellows |
| 1,080 Associates |
| <hr/> |
| 3,902 Total |

"During the past year, since our last Annual Session, 199 have been elected to Fellowship and 275 to Associateship. All but a very few of those elected to Fellowship were advanced from Associateship.

"Since the last Annual Session, we have lost through death, 58 members, consisting of 1 Master, 47 Fellows and 10 Associates.

"4 resignations of Fellows and 10 resignations of Associates, the latter due primarily to inability to qualify for Fellowship, have been accepted.

"All but about 7 per cent of those elected to Associateship five years ago qualified for Fellowship.

The number who have taken advantage of Life Membership has been steadily growing. Since the last Annual Session, 22 have subscribed to Life

Membership, making a grand total of 101. However, due to deaths of 4 Life Members, there remain 97. The names of the Life Members of the College are not only entered in the Directory of the College, but their names appear on the Life Membership Scroll, which is exhibited in the College Booth, space No. 36, in the Exhibit Room."

Upon motion duly seconded and carried, the report of the Secretary-General was accepted.

On behalf of the Board of Regents, in consideration of his services as President of the College, the Secretary-General, Dr. Piersol, presented to the outgoing President of the American College of Physicians, Dr. James H. Means, a silver, engraved, ferruled Gavel. Dr. Means accepted the Gavel and expressed his deep appreciation therefor.

At this point, Dr. Means called upon the incoming President, Dr. William J. Kerr, to take over the chairmanship of the meeting.

Dr. Kerr, in taking the chair, addressed the College as follows:

"I feel very humble in standing before you today to accept this high office in the College. It is a little more than a year ago when I began to receive some letters from friends congratulating me upon my election, or selection for the Presidency of the College. I had not seen notice in the *ANNALS*. That was the first intimation that any such honor could ever come my way. I must say that I was greatly surprised and I still don't understand.

"During this year of preparation for the job which lies ahead, I have felt a good deal of temerity in assuming the position, and when I have thought of the very distinguished men who have preceded me in this position and noted their accomplishments, I had hoped that I might be able to rise to the occasion.

"If you do not mind some references which I may now make, and not in a facetious mood, because this is a very serious moment in my life, I would like to liken the College to a certain long-necked bird, a land bird, if you will, one which goes rather steadily in a forward direction but with a long neck and head on the end which may be represented by your President, moving about a little here and there from side to side and up and down, but still the old bird moving steadily forward.

"This is a ground bird and the wings are not developed for flight. The chief organ of this bird is the gizzard, which accepts all manner of things which are provided and brought before it, and this is represented by our honorable Board of Regents and Governors who have to pass upon many and sundry things presented, and I must say through my brief experience on this Board that I never saw a group of men who could master problems in a more efficient manner.

"The plumage of this bird is represented by the Fellows and Associates of the College who can be recognized throughout the length and breadth of our land, including Canada and other countries near-by, because of their outstanding accomplishments which everyone in the community can well recognize.

"The chief means of defense of this particular bird is the long leg with strong toes which is provided only for a frontal attack. This bird cannot kick backwards, but only by a frontal attack can it meet its enemies and meet the problems which arise, and we are, I think, hoping that in the College we may be able to continue to anticipate danger ahead or problems ahead and meet them squarely when they come.

"Through the great speed of this bird, it has not been necessary to prepare defenses toward the rear. I may say, so far as I can understand the position of the College in the country today, we are rapidly outstripping all of our competitors.

"By now, I think you will recognize that this bird is a male, and since it is the custom among this species for the male to sit on the nest and hatch the eggs, in our College there have been several notable hatchings, chief among them now classed as our living offspring are the ANNALS OF INTERNAL MEDICINE, the College home with its very efficient staff presided over by Mr Loveland, the American Board of Internal Medicine, not yet full grown but developing well and rapidly, for the certification of internists in this country, then our educational features, chief among which during the past many years have been our Annual Sessions, and more recently the regional meetings throughout the country

"During the last year, we have added the postgraduate effort in the College and from the response which we had this year, even though we had a late start, we are encouraged to believe that this may prove to be one of the most successful and helpful of our endeavors for the membership in the College. It shows an abiding interest in keeping up that which has always distinguished the members of the profession in our special field

"We are hoping during the next year to increase our activities in this direction and perhaps to make some surveys in cooperation with other agencies on the possibilities for postgraduate instruction in this country

"It is hoped, in returning to the bird, that your President as the temporary and roaming head of this great organism may be able to keep his head out of the sand. He is a little beyond the place of the shifting sands in this country today, but it is to be hoped that he will keep awake to situations arising in the country

"If I can bring to the College the spirit of our last and rapidly diminishing frontier in the West, I shall be very happy. If the impressive water falls, the giant peaks and trees of the West have any influence upon land, then I hope that I may be able to translate some of it into activity upon behalf of the College as a whole

"There are two things which are very close to my heart in relation to the College. One of them is the matter of postgraduate training upon which we have already embarked, but in a very small way. There is another matter with respect to the dues. We hope that after due deliberation we may find some way to reduce the annual dues for members in the College. It may not be much, but we hope that it may be able to be accomplished

"In concluding these remarks, I wish to assure you that I shall labor diligently for the whole College, and I hope that I shall not let you down during my year in office. Thank you!"

Upon motion duly seconded and carried, it was

Resolved, that in accordance with the present By-Laws of the American College of Physicians and directions of the Board of Regents at a regular meeting held on April 18, 1937, and in accordance with the publication of such proposed amendment to the members in accordance with the present By-Laws, an addition shall be made to the By-Laws, Article IV, Section 1, as an additional paragraph, as follows

"Any member of the Board of Governors unable to attend the Annual Session shall appoint as his alternate, with all the privileges of a Governor, a Master or Fellow of his district who will be in attendance at that Session. Upon presentation to the Chairman of the Board of Governors of a certificate of appointment, the alternate shall be recognized and act in the full capacity of Governor for the Session to which he has been appointed. The same alternate shall not be appointed for more than two consecutive years"

President Kerr then called for a report of the Committee on Nominations by the Chairman, Dr Jonathan C Meakins, whose report herewith follows

" Mr President

I beg to report on behalf of the Nominating Committee

In accordance with the By-Laws, Article I, Section 2, we submit the following names

(A) For the Elective Offices

| | |
|------------------------------|------------------------------------|
| <i>President-Elect</i> | O H Perry Pepper, Philadelphia, Pa |
| <i>First Vice-President</i> | James B Herrick, Chicago, Ill |
| <i>Second Vice-President</i> | Noble Wiley Jones, Portland, Ore |
| <i>Third Vice-President</i> | Charles T Stone, Galveston, Tex |

This list of nominees has been duly published in the ANNALS OF INTERNAL MEDICINE at least one month before the present date

(B) For the Board of Regents

For the Term Expiring 1940

David P Barr St Louis, Mo

For the Term Expiring 1941

James E Paullin, Atlanta, Ga
Robert A Cooke, New York, N Y
Hugh J Morgan, Nashville Tenn
Ernest E Irons, Chicago, Ill
D Sclater Lewis, Montreal, Que

(C) For the Board of Governors

For the Term Expiring 1940

| | |
|----------------|----------------|
| Eugene H Drake | MAINE—Portland |
| M D Levy | TEXAS—Houston |

For the Term Expiring 1941

| | |
|---------------------|-----------------------------------|
| James F Churchill | SOUTHERN CALIFORNIA—San Diego |
| James Waring | COLORADO—Denver |
| Francis G Blake | CONNECTICUT—New Haven |
| Wallace M Yater | DISTRICT OF COLUMBIA—Washington |
| Samuel E Munson | SOUTHERN ILLINOIS—Springfield |
| Robert M Moore | INDIANA—Indianapolis |
| Thomas Tallman Holt | KANSAS—Wichita |
| William B Breed | MASSACHUSETTS—Boston |
| Warren Thompson | NEBRASKA—Omaha |
| Leander A Riely | OKLAHOMA—Oklahoma City |
| Nelson G Russell | WESTERN NEW YORK—Buffalo |
| R R Snowden | WESTERN PENNSYLVANIA—Pittsburgh |
| Edward L Bortz | EASTERN PENNSYLVANIA—Philadelphia |
| John L Calene | SOUTH DAKOTA—Aberdeen |
| J Owsley Manier | TENNESSEE—Nashville |
| Louis E Viko | UTAH—Salt Lake City |
| Harry L Arnold | HAWAII—Honolulu |
| J H Holbrook | ONTARIO—Hamilton, Canada |
| C F Moffatt | QUEBEC—Montreal, Canada |
| William M James | PANAMA and the CANAL ZONE " |

President Kerr then asked if there were other nominations to be made from the floor. There were none, and upon motion duly seconded and unanimously carried, it was

Resolved, that the nominations be closed and that the secretary cast the ballot for the election of the nominees presented by the Nominating Committee.

President Kerr then asked for the presentation of other business, whereupon the following resolution, offered by Dr. Jonathan C. Meakins, was duly seconded and unanimously carried with a rising vote:

Resolved, that the cordial thanks of the American College of Physicians be extended to the Retiring President, Dr. James H. Means, to the General Chairman, Dr. James Alex. Miller, and to the Vice Chairman and members of his various committees, individually and collectively, for their faithful work in the preparation and conduct of the New York Session, to the Ladies Entertainment Committee for their efficiency and courteous entertainment of our visiting ladies, to the medical schools and hospitals of New York City for putting their facilities at the disposal of the College, and for their helpful participation, to the New York Convention Bureau and its Director for their assistance, and the Waldorf-Astoria Hotel and its Convention Manager for their cooperation.

Adjournment

EXECUTIVE SECRETARY'S REPORT

1937

The auditor's report of his examination of the accounts of the College is hereto attached. Even with added activities affecting the finances of the College, such as the gift of one thousand dollars to the National Conference on Nomenclature of Diseases and the writing off of one thousand dollars as depreciation on the Headquarters Building, as directed by the Board of Regents, the surplus is still favorable as below indicated:

| | |
|--------------|--------------|
| 1935 Surplus | \$ 17,182 09 |
| 1936 " | 24,946 53 |
| 1937 " | 23,765 75 |

The 1937 surplus was distributed as follows:

| | |
|----------------|--------------|
| Endowment Fund | \$ 2,749 45 |
| General Fund | 21,016 30 |
| | <hr/> |
| | \$ 23,765 75 |
| | <hr/> |

The total principals of the two Funds on December 31, 1937, were:

| | |
|----------------|--------------|
| Endowment Fund | \$ 64,534 27 |
| General Fund | 140,849 20 |
| | <hr/> |
| | \$205,383 47 |
| | <hr/> |

For comparison, the total assets of the College in 1926 were only \$9,000 00. The growth of the activities and services of the College has been greatly expanded during the intervening years, yet there has been built up an excellent financial foundation. Conservative policies and aggressive effort are responsible, although the general momentum and natural growth have contributed much in recent years. The

journal, *ANNALS OF INTERNAL MEDICINE*, was for many years the source of considerable deficits. Volume I showed but ten and three-quarters pages of paid advertising, Volume X (completed, June 1937) showed two hundred and sixty-seven pages of paid advertising. Volume I had an average circulation of 1803, Volume X, 3878. The March, 1938, issue (Vol XI, No 9) had a circulation of 4210. But the College has also given its members more as the journal grew, Volume I had 1040 pages of scientific content, Volume X, 1786 pages.

During 1937 a new and revised Directory of the College was published in accordance with recommendations of the Board of Governors and the Board of Regents. The Directory contains 621 pages, and was published at a total cost, including cost of distribution, of slightly over \$4,000.00. The cost in labor and funds is well justified by its wide use by members of the College, medical societies, medical schools, hospitals, insurance companies and other agencies.

The budgets for 1938 were approved in detail by the Board of Regents December 12, 1937.

Respectfully submitted,

(Signed) E R LOVELAND,
Executive Secretary

March 4, 1938

To the Board of Regents

American College of Physicians, Inc
Philadelphia, Pa

Mr E R Loveland, Executive Secretary

Dear Sirs

I have examined the accounts of the

AMERICAN COLLEGE OF PHYSICIANS, INC

for the year ended December 31, 1937, and the accompanying statements, including the Balance Sheet at December 31, 1937, the analyses of the General Fund and the Endowment Fund and the Detailed Statement of Operations for the year ended December 31, 1937, are in accordance with the books of account and in my opinion set forth correctly the financial position at December 31, 1937, and the results of operations for the calendar year ended December 31, 1937, subject to the following comments:

Cash The cash was properly accounted for. The following is a statement of the cash in the various depositories:

| | |
|---------------------------------------|------------|
| Girard Trust Company, Philadelphia | \$2,313 75 |
| Provident Trust Company, Philadelphia | 861 47 |
| Royal Bank of Canada, Montreal | 741 82 |
| | <hr/> |
| | \$3,917 04 |
| | <hr/> |

The amount of cash in closed banks at January 1, 1937, was \$6,292 39, during the year a liquidating dividend amounting to \$583 06 was received, which reduced the amount to \$5,709 33, as shown by the following schedule

| | <i>Balance Jan 1, 1937</i> | <i>Liquidating Dividend</i> | <i>Balance Dec 31, 1937</i> |
|------------------------------------|--------------------------------|---------------------------------|---------------------------------|
| Bank of Pittsburgh, Pittsburgh | \$1,461 97 | | \$1,461 97 |
| Exchange National Bank, Pittsburgh | 1,749 20 | \$583 06 | 1,166 14 |
| Highland National Bank, Pittsburgh | 3,081 22 | | 3,081 22 |
| | <u>\$6,292 39</u> | <u>\$583 06</u> | <u>\$5,709 33</u> |

Accounts Receivable The accounts receivable were examined and found to be less than one year old and appear to be good and collectible. The detailed accounts receivable were in agreement with the control account. No requests for confirmation of the accounts were mailed.

Investments The securities were accounted for by direct correspondence and the income for the period under review was verified.

General The increase in the amount of the Endowment Fund and the General Fund during the year 1937 is as follows

| | <i>Balance Jan 1, 1937</i> | <i>Net Increase</i> | <i>Balance Dec 31, 1937</i> |
|----------------|--------------------------------|-------------------------|---------------------------------|
| Endowment Fund | \$ 61,784 82 | \$ 2,749 45 | \$ 64,534 27 |
| General Fund | 119,832 90 | 21,016 30 | 140,849 20 |
| | <u>\$181,617 72</u> | <u>\$23,765 75</u> | <u>\$205,383 47</u> |

In accordance with the instructions of the Executive Secretary, the prepaid insurance at December 31, 1937, was not set up as a deferred expense, the other deferred and accrued items were verified, the charges to the College Headquarters account were examined, and in my opinion appear to be proper charges to this account, the charges to the Furniture and Equipment accounts represent proper additions to this account and the allowance for depreciation appears to be adequate, a depreciation reserve account has been set up for the new building in accordance with the action of the Board of Regents at the meeting on December 12, 1937, which provided that depreciation on the building should be taken into account at the rate of \$1,000 00 per year, the footings and extensions of the inventory were verified, all ascertainable liabilities have been included in the balance sheet, all recorded receipts from dues, initiation fees, exhibits, advertising, sales of publications, etc., were properly deposited in bank and all disbursements, as indicated by the vouchers, cancelled checks and bank statements, were properly recorded in the books of account.

Very truly yours,

(Signed) H I MacLEAN,
Certified Public Accountant

REPORT ON REGISTRATION OF THE
TWENTY-SECOND ANNUAL SESSION
OF THE
AMERICAN COLLEGE OF PHYSICIANS
New York, N Y April 4-8, 1938

Below appears a distribution of the registration at the New York Session of the College. The member attendance was the highest at any meeting in the history of the College. The guest attendance was restricted very largely to guest clinicians and speakers, since the physical facilities could not accommodate the large number of guests that would attend if admission were open to all members of the local county medical societies in the district.

The New York registration compares with previous registrations as follows:

| <i>Session</i> | <i>Members</i> | <i>Guest Physicians</i> | <i>Students</i> | <i>Ex- hibitors</i> | <i>Guest Non- Physicians</i> | <i>Visiting Ladies</i> | <i>Total</i> |
|---------------------|----------------|-----------------------------|-----------------|-------------------------|--------------------------------------|----------------------------|--------------|
| NEW YORK (1938) | 1447 | 463 | 3 | 291 | 24 | 319 | 2,547 |
| ST LOUIS (1937) | 877 | 589 | 414 | 201 | 30 | 210 | 2,321 |
| DETROIT (1936) | 733 | 539 | 172 | 132 | | 103 | 1,679 |
| PHILADELPHIA (1935) | 923 | 749 | 346 | 231 | | 195 | 2,444 |
| CHICAGO (1934) | 690 | 660 | 420 | 194 | | 121 | 2,085 |

SPECIAL LOW SUMMER RATES FOR ARTHRITICS

The Desert Sanatorium will admit patients suffering from arthritis between May 15 and July 15, 1938, at the all-inclusive rate of \$150.00 per month which will include room with private bath and private screened porch board with tray service to the room medical care and nursing service physiotherapy, transfusions (except the fee to the blood donor) diagnostic studies (x-rays laboratory tests etc) and all other expenses incident to their treatment

These rates will apply exclusively to sufferers from arthritis and all patients admitted will be required to remain three months, unless sooner discharged by the Medical Director Regular rates will be restored October 15 1938 These reduced rates are being offered

1 To enable arthritic patients of moderate means to make use of the complete facilities of this institution during the warmer months when maximum climatic benefit may be expected

2 To continue the clinical studies being made by the Sanatorium staff of arthritis particularly as affected by climatic conditions

3 To maintain employment for certain members of the Sanatorium staff who otherwise would not be retained during the summer months

THE AMERICAN COLLEGE OF PHYSICIANS

4200 PINE STREET

PHILADELPHIA, PA.

Fellowship Insignia for Academic Gown

The insignia for academic dress was
adopted after exhaustive investigation by
a special committee on insignia of the
College. It consists of a cross of the
shape of the Fellowship Key, exact size
as illustrated, of green velvet with the
Seal of the College outlined in solid gold
braid, to be worn at the option of the
Fellow on the right sleeve of the aca-
demic gown, about three inches below the
shoulder seam. These insignia are made
up on order ready to be stitched to the
gown.

Price, delivered, \$4 00

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts., Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md.

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physicians. The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College.

MANUSCRIPTS All correspondence relating to the publication of papers and all books and monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following style.

4 DOE, J E. What I know about it, Jr. Am Med Assoc, 1931, xcvi, 2006-2008

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations.

REPRINTS For each article published, there will be furnished gratis fifty reprints without covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are wanted the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and books bearing upon the field of internal medicine. Authors and publishers wishing to submit such material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made in the department of reviews.

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid: \$7.00, United States, Canada, Mexico, Cuba, Canal Zone, Hawaii, Porto Rico, \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. Members of the American College of Physicians receive the ANNALS OF INTERNAL MEDICINE as a part of their membership. Checks should be drawn to the order of W. D. STROUD, M.D., Treasurer, and remitted through the Publication Office or the Executive Secretary's Office.

BUSINESS CORRESPONDENCE All correspondence relating to business matters, advertising, subscriptions to the ANNALS, inquiries concerning membership in the American College of Physicians, et cetera, should be addressed to the Publication Office or to the Executive Secretary. Books and reprints presented to the College Library should be addressed to the Executive Secretary.
